Question 31 of 280

A 30 year-old HIV positive South African woman presents to the emergency department with a 12 day history of fever and headache. On examination she is found to have a 6th nerve palsy, papilloedema and erythematous skin papules across her torso. She is not on any medication.

Investigations:

CD4 count	90 cells / mm ³
-----------	----------------------------

CT head: Normal

What is the most appropriate immediate management?

	Intravenous ceftriaxone
	Anti-retroviral therapy
	Rifampicin, isoniazid, pyrazinamide & ethambutol
	Intravenous albendazole & hydrocortisone
	Intravenous amphotericin B & flucytosine

□ Question 32 of 280

A 56-year-old female was admitted to the Emergency Department with a 90-minute history of new onset weakness in her left arm and leg. She stated that she was out shopping when the weakness suddenly came on. Since the onset of the weakness she has noticed some regained strength but still felt definite weakness. She had a past medical history comprising new atrial fibrillation for which she was undergoing investigation, hypertension, hypercholesterolaemia and asthma. She also had a perforated gastric ulcer 16 years ago. She was prescribed amlodipine 5mg OD, bisoprolol 2.5mg OD, atorvastatin 20mg OD, Clenil modulite 200mcg BD and aspirin 75mg OD. She declined formal anticoagulation regarding her atrial fibrillation. When questioned specifically, she denied the presence of any visual loss, headache, vomiting, loss of consciousness or cardiac symptoms. She smoked 20 cigarettes per day and did not consume alcohol.

On examination she was alert and walking with a hemiplegic gait. Her blood pressure was 168/74 mmHg, heart rate 78bpm, respiratory rate of 18/min, temperature of 37.2 C and oxygen saturations of 99% on air. Other than an irregularly irregular pulse, examination of the cardiovascular, respiratory and gastrointestinal systems were unremarkable.

Examination of the central neurological system revealed normal cranial nerves 2-12, with equal and reactive pupils, normal fundoscopy and a GCS of 15. Examination of the peripheral nervous system revealed the presence of power 3/5 in all muscles of the left upper and lower limbs, with decreased tone and absent deep reflexes. Power was otherwise 5/5 in all other muscle groups, with downgoing plantar reflexes. Sensation and coordination testing was unremarkable.

Initial investigations revealed the following results:

Hb	179 g/l
MCV	99 fl
Platelets	452 * 10 ⁹ /l
WBC	12.2 * 10 ⁹ /l

ECG: atrial fibrillation 74 bpm no acute changes

CT head scan: no evidence of intracranial haemorrhage, mass shift or space occupying lesions

What is the next best management step?

Commence intravenous heparin

	Commence thrombolysis therapy
	Arrange urgent haematology consult
	Commence aspirin 300mg and admit to stroke unit
	Commence immediate amlodipine 5mg OD

Dashboard

□ Question 33 of 280

□ □

A 74-year-old female has been admitted to the stroke unit following a significant right middle cerebral artery infarct. A dense left side sensori-motor syndrome and significantly impaired swallowing mechanisms were noted. Nursing staff insert a nasogastric (NG) tube after the patient failed her swallow screen and NG feed is immediately started. Around 72 hours after the feed was commenced, her blood sugar was noted to be 16 mmol/l, with no serum or urinary ketones. Her only past medical history was paroxysmal atrial fibrillation and no known diagnosis of diabetes mellitus. She took aspirin 75mg only prior to admission. What is the optimal management of her hyperglycaemia?

	Prescribe 6 units actrapid as required when BM > 10 mmol/l
	Stop the NG feed
	Prescribe biphasic insulin twice daily
	Prescribe warfarin as per loading regime
	Repeat the BM in 4 hours time, no action at present

□ Question 36 of 280

□ □

An 82-year-old female is brought into your falls clinic by her daughter after her third fall this year. No fractures were sustained and she appears to have no significant head injuries. The fall appears mechanical in nature. She currently lives with her daughter, who reports the patient's mobility to be progressively deteriorating, from full independence and no exercise limitations 1 year ago to restrictions at 50-70 yards now, limited by knee pain secondary to osteoarthritis. Her other past medical history includes hypertension, type 2 diabetes mellitus, chronic kidney disease and previous gallstones.

You note she is withdrawn and makes little eye contact. Her voice is quiet. When you ask her whether she is low in mood, she does not respond. She reports no suicidal ideations but has little hope for the future. She asks you to 'not worry about it', as she 'has been the same way for several months now'. However, the patient does seem amenable to some kind of treatment.

On the Beck depression scale, she scores 11/63 (0-13 = no or minimal depression), on the geriatric depression scale, she scores 11/15 (greater than 10 = indicative of depression) and mini-mental state examination, she scores 19/30 (20-26 = mild cognitive impairment, 10-19 = moderate cognitive impairment). Routine investigations including B12, folate, thyroid function, liver function tests and bone profile are unremarkable.

What is the most appropriate treatment pathway?

	Citalopram
	Amitriptyline
	Mirtazapine
	Donepezil
	No treatment required

Question 37 of 280

A 23 year old female has re-presented 2 days after discharge from the neurology team with a constant diffuse headache, worse on standing than lying down, without neck stiffness or photophobia, but associated with nausea and vomiting. 48 hours ago, she was an inpatient being investigated for intermittent headaches over the past 8 months, typically over the left side of her frontal and temporal regions, of sudden onset during any time of day, associated with double vision, lasting for 'hours' at a time. She was experiencing up to 5 episodes a week, with one episode witnessed during her admission, when the senior house officer noted bilateral restriction in vertical eye movements, adduction and unreactive pupils, spontaneously resolving after 3 hours. Her blood tests were unremarkable.

The patient underwent a CT head, demonstrating no intracranial lesions; and a lumbar puncture:

Opening pressure	12.3 cmH ₂ O
WCC	2 /mm ³
RBC	50 /mm ³
Protein	0.45 g/l
Glucose	4.5 mmol/l (serum 6.7 mmol/l)
Oligoclonal bands	None present

The patient subsequently self-discharged, reporting no immediate headaches, back pain or lower limb paraesthesiae after the lumbar puncture.

During this second admission, she undergoes a MRI head scan, demonstrating significant diffuse meningeal enhancement and bilateral shallow subdural haemorrhages. What is the appropriate treatment?

	Oral fluids, caffeine and blood patch
	Repeat lumbar puncture
	Intravenous aciclovir

	Intravenous ceftriaxone
	Neurosurgical input

Dashboard

Question 38 of 280

A 32-year-old woman presents with reduced sensation. She has noticed that slowly over six months she has not felt when hot water has splashed on her hands, despite blistering occurring afterwards. Her husband has become concerned and asked her to seek a medical opinion. She denies any other problems, including weakness, weight-loss or her activities of daily living being affected. She has a past medical history of asthma but only rarely needs her salbutamol inhaler. She has no other medications or allergies. On examination, she has sensory loss over her hands and arms when tested for temperature and pain. There is a dermatomal distribution affecting dermatomes C4 to C6 which is symmetrical. Cranial nerve and lower limb examination is normal. Spinal examination shows no tenderness. What is the most likely diagnosis?

	Multiple sclerosis
	Cervical disc prolapse
	Vasculitis
	Myasthenia gravis
	Syringomyelia

□ Question 41 of 280

□ □

An 18-year-old lady works as a nursery teaching assistant and has noticed her right arm always shakes as she stretches it out to write on the blackboard at school. She has also started dropping cups of tea because of shaking on picking them up. Her balance has become poor and she now falls over easily when playing hopscotch with the children. These problems have developed over 14 months slowly. Her neurological examination reveals a postural tremor of the upper limbs; right worse than left, as well as a broad-based ataxic gait. She has some co-existent rigidity of the right upper limb. Slit lamp examination reveals brown-green deposits in Descemet's membrane of the cornea. The remainder of the clinical examination is unremarkable. What is the most appropriate treatment for the underlying condition?

	Dimercaprol
	Levodopa
	Beta-interferon
	D-penicillamine
	Calcium EDTA

A 55-year-old female presents with 3 weeks of bilateral tingling sensation in her medial one and half digits at night. She has noted a clawing of her 4th and 5th digits and she is particularly concerned by the cosmetic elements. She also complains of a left sided foot drop present over the past 8 months. Her past medical history includes type 2 diabetes mellitus, for which she take metformin 850mg TDS and she admits to occasional poor compliance. Her last HbA1c was 7 mmol/l. She has also had multiple admissions for surgery to her feet at childhood but she is unaware of further details. She was adopted and is unaware of her birth family history. On examination, she clinically has a left common peroneal palsy with bilateral thin calves, and loss of sensation in bilateral ulnar nerve territories. What is the unifying diagnosis for her presenting paraesthesia and foot drop?

	Hereditary neuropathy with liability to pressure palsies
	Diabetic neuropathy
	Chronic inflammation demyelinating polyneuropathy (CIDP)
	Systemic lupus erythematosus (SLE)
	Sarcoidosis

Question 43 of 280

A 35-year-old lady with no significant past medical history presents to you with lethargy and fatigue over several years, often finding she does not sleep well at night. She complains of a sensation of discomfort in her lower extremities at rest, particularly worse when she is trying to fall asleep. She also describes an abnormal crawling and itching sensation below the knees and often walking will relieve her symptoms. There is no history of pain or night time snoring. Clinical examination and routine blood investigations are unremarkable. She tells you that over the years her general practitioner has ordered several tests on her that have all been normal, including brain imaging, thyroid function, and monitoring of her haemoglobin levels. She is not on any medications. She is now struggling to do her job as a teacher and is now working only part time because of the symptoms. Considering the likely underlying diagnosis, which of the following would you use to try and alleviate her symptoms?

	Lithium
	Quinine
	Pramipexole
	Amitriptyline
	Acetazolamide

□ Question 44 of 280

A 73-year-old man who is a chronic alcoholic is brought to the Emergency Department by an ambulance. He was found collapsed in the street. On admission his airway, breathing and circulation are satisfactory. His GCS is 13/15 (eyes = 3, verbal = 4, movement = 6) although his level of consciousness appears to be fluctuating. There are no obvious signs of external head injury.

A CT head (without contrast) is performed:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

Subarachnoid haemorrhage

	Wernicke's encephalopathy
	Subdural haematoma
	Meningioma
	Extradural haematoma

□ Question 45 of 280

A 45-year-old man complains of lower limb numbness associated with weakness. He also noted some recent problems with urinary incontinence and has recently attended the opticians due to some blurring of vision

On examination he has bilateral lower limb weakness (grade 3+/5). His tone was spastic on both sides with exaggerated reflexes. The planter reflexes were up-going bilaterally. The sensory level was at the tenth thoracic vertebra (T10). Eye examination revealed a normal visual acuity with a normal fundal examination.

He has a history of asthma and is currently well controlled with just a salbutamol inhaler.

Magnetic resonance imaging (MRI) of the brain is normal. MRI of the spine shows a hyper intense lesion spanning from (T7-T12). The following investigations had been ordered:

Na+	135 mmol/l
K+	4 mmol/l
Creatinine	80 µmol/l
Urea	4.5 mmol/l
CRP	5 mg/l
ESR	10 mm/hr
Urine analysis	Normal
ANA	Negative

Which one of the following investigations would be most useful to reach a diagnosis?

	Auditory evoked response potentials
	CSF analysis for oligoclonal bands
	Anti-aquaporin 4 antibodies

	Serum B12
	Visual evoked response potentials

Dashboard

Question 46 of 280

An 18-year-old female is admitted to hospital with worsening lower limb weakness. She states that it started in her ankles, but now she is unable to stand from a squatting position which is abnormal for her. On examination, she has reduced power in ankle plantar and dorsiflexion bilaterally as well as some mild weakness in her hip extensors. Her hand grip strength is normal.

A cerebrospinal fluid (CSF) study is carried out and based on the clinical syndrome and the result she is diagnosed with Guillain-Barre Syndrome (GBS).

Which of the following treatments should be commenced in the acute setting?

	Intravenous methylprednisolone
	Intravenous immunoglobulin
	Oral prednisone
	Rituximab
	Pyridostigmine

□ Question 47 of 280

A 65-year-old man attends neurology clinic for review of his long-standing trigeminal neuralgia. He had first experienced symptoms five years previously and been troubled by his illness ever since despite frequent neurology review. The patient experiences attacks of severe shooting pain affecting the right side of his lower face, each episode usually lasting about one hour. The interval between attacks has steadily reduced over the years so that at the present time the patient experiences four to five episodes per week. The patient describes that his symptoms are profoundly limiting his life and that he rarely leaves his house for fear of an attack.

Four years previously, treatment with carbamazepine had been introduced with an initially good response to symptoms. However, patient proved to be intolerant of carbamazepine due to drowsiness. Subsequent trials of treatment with oxcarbazepine, lamotrigine and baclofen had not given lasting relief.

The patient had recently been diagnosed with depression and initiated on treatment with sertraline. He was also suffered from type 2 diabetes currently managed with diet and metformin 500 mg TDS. The patient lived with his wife and had been unable to work as a school-teacher for the past two years due to his symptoms.

Having previously been reluctant to consider surgical intervention, the patient now felt he would be willing to try any options that could improve his symptoms.

MRI brain with / without contrast: sinuses unremarkable without evidence of inflammation; no space occupying lesion; no extra-cranial mass along course of trigeminal nerves; no evidence of widespread demyelination plaque; no evidence of previous infarction; no abnormal enhancement of the trigeminal nerves.

What is the appropriate surgical intervention for this patient?

	Stereotactic radiosurgery
	Balloon compression
	Microvascular decompression
	Radiofrequency lesioning
	Glycerol rhizolysis

Dashboard

□ Question 48 of 280

A 59-year-old male presents with 4-day history of sudden onset visual disturbance in his right eye. He reports it to be his first episode with no previous history of visual problems. His past medical history includes type 2 diabetes mellitus, hypertension and raised BMI. He is an active smoker of 40 pack years.

On examination, a right relative afferent papillary defect is detected. Pupils were equal in size. A visual field defect is demonstrated in the inferior nasal field of the right eye without a precise quadrantanopia or altitudinal pattern. Temporal arteries are non-tender and not thickened. Visual acuity on Snellen chart in left eye was 6/6, 6/18 in right. Colour vision on Ishihara plates were 17/17 on left, 5/17 on right. Fundoscopy is unremarkable. Examination of the upper and lower limbs are unremarkable, no language deficits are noted. Auscultation revealed normal heart sounds and no bruits.

His blood tests are as follows:

Hb	154 g/l
Platelets	$190 \times 10^9/l$
WBC	$7.8 \times 10^9/l$
ESR 5 mm/hr	

Na ⁺	141 mmol/l
K ⁺	3.9 mmol/l
Urea	5.6 mmol/l
Creatinine	80 μ mol/l

What is the most likely diagnosis?

	Right retinal infarct
	Right temporal arteritis

	Right non-arteritic ischaemic optic neuropathy
	Left middle cerebral artery ischaemic stroke
	Left occipital ischaemic stroke

□ Question 49 of 280

□ □

A 65-year-old male presents to the neurology outpatient department with a history of recurrent bouts of unsteadiness and vomiting over the last 10 years, with partial resolution. He has also had episodes of visual problems, which he describes as the sudden loss of vision in the right eye, with an almost complete recovery of vision over the course of the next few weeks. He has a history of type 2 diabetes and is hypertensive and is generally non-compliant with his treatment. He is also a smoker with a 50 pack year history.

His medication includes glimepiride 2mg daily and metformin 500mg TDS. He also takes telmisartan 40mg daily.

On examination, he has nystagmus in the right eye with the fast component towards the right. His gait is ataxic and he has evidence of spasticity in both lower limbs with exaggerated reflexes and bilateral ankle clonus. Fundoscopic examination revealed a pale optic disc.

MRI brain shows diffuse lesions in multiple sites. The report queried demyelinating plaques vs multiple infarcts.

Which of the following would be the most appropriate next investigation?

	MRI spinal cord
	CSF examination for oligoclonal bands
	MR angiography of the vertebrobasilar system
	Titres of anti-Hu antibodies
	Visual evoked potentials

Question 50 of 280

A 35-year-old female presents to the Emergency Department with three days of increasing weakness in the left arm and reduced visual acuity in the left eye. She was diagnosed with relapsing-remitting multiple sclerosis two years earlier. She takes fingolimod as maintenance therapy and denies any compliance issues.

On examination, she has weakness in wrist extension and finger abduction in the left hand and visual acuity in the left eye was measured at 6/24 with an associated reduction in colour saturation. Her blood tests were unremarkable and in particular, her white cell count was normal. Her MRI scan does show two new enhancing lesions in the right pericallosal region.

How should this be managed acutely?

	Commence high dose oral prednisone and wean over a month
	Commence intravenous dexamethasone
	Commence natalizumab infusion
	Commence high dose methylprednisolone for 3-5 days
	Biopsy the enhancing lesions

Dashboard

Overall score: 0%

□ Question 52 of 280

□ □

A 20-year-old woman presents to a general neurology clinic. Over the last year, she has noted that she is becoming increasingly clumsy with heavy objects. She describes struggling to wash her hair and complete certain house hold chores such as hanging washing up.

Neurological examination findings of the upper limbs have been summarised below. Power has been recorded as per the Medical Research Council (MRC) grading system.

	Left arm	Right arm
Tone	normal	normal
Power:		
shoulder abduction	3/5	3/5
shoulder adduction	4/5	4/5
elbow flexion	4/5	5/5
elbow extension	5/5	5/5
wrist flexion	5/5	5/5
wrist extension	5/5	5/5
Reflexes:		
Biceps	normal	normal
Triceps	normal	normal
Supinator	normal	unable to elicit
Sensation	intact	intact

When examining her cranial nerves it is noted there is drooping of her eyelids and decreased facial expression. Tests for fatigability were unremarkable. There were no other abnormal findings.

What is the most likely diagnosis?

	Myasthenia gravis
	Facioscapulohumeral dystrophy
	Multiple sclerosis
	Miller-Fisher syndrome
	Becker's muscular dystrophy

□ Question 53 of 280

□ □

A 54-year-old woman is admitted to the Emergency Department after having a seizure. This occurred whilst she was a passenger in a car. There is no history of trauma. By the time of her admission she is alert with a GCS of 15/15. Her partner describes a generalised seizure with a post-ictal phase lasting around 30 minutes.

On examination her heart rate is 90/min, blood pressure 102/60 mmHg and temperature 37.1°C. There are no focal neurological signs.

A MRI scan is requested:

□ Question 54 of 280

□ □

A 57 year old male presents with a three month history of unintentional weight loss (13kg over 3 months) and a chronic non-productive cough. He has just returned from a months holiday in India. He denies haemoptysis or chest pain. He is a lifelong non-smoker. He has no past medical history except a period of generalised limb weakness four years ago, when he was referred to outpatient neurology clinic and prescribed 3,4 diaminopyridine following investigations. His blood tests are unremarkable. However, his CXR demonstrates a rounded opacity in his right mid zone, about 2 cm from his right main bronchus. What is the diagnosis?

	Tuberculosis
	Aspergilloma
	Small cell lung carcinoma
	Non-small cell carcinoma
	<i>Pneumocystitis Jirovecii</i> infection

Question 55 of 280

A 48-year-old male presents with a sudden onset occipital headache onset 2 and half hours ago, associated with slurred speech, vomiting and unsteadiness in all movements. In the 90 minutes after admission to the emergency department, it was noted that the patient became increasingly drowsy, deteriorating from a GCS of 15 on admission to E3 V4 M5. On examination, pupils are equal, his speech is dysarthric and bilateral plantars are downgoing. You are unable to elicit more formal power, tone or sensation examination in the patient. An initial CT head is unremarkable but a subsequent MRI head with diffusion weighting sequences demonstrates restricted diffusion in bilateral cerebellar hemispheres with significant swelling around the cerebellum, brainstem and aqueduct. GCS currently 14/15 at 10 hours post-event. You have initiated aspirin 300mg and inserted a nasogastric tube. What is the appropriate management?

	Add clopidogrel 300mg
	Start warfarinisation
	Thrombolysis
	Discuss with neurosurgery for decompressive posterior craniectomy
	Hourly neuro observations with empirical anti-seizure medications

Question 56 of 280

□ □

A 26 year old female presents with a 4 month history of continuous left sided facial pain and fronto-temporal headache. She reports it to be constantly present and throbbing in nature, with exacerbations of worsened severity every 3 days. She reports exacerbations to typically be associated with injected left eye and left nasal congestion, with occasional teariness in her left eye.

She has no past medical history or drug history except the oral contraceptive pill. Her routine blood tests are unremarkable. A MRI head organised by her GP also demonstrated no intracranial pathology. An trial indomethacin you have organised is positive.

What is the most likely diagnosis?

	Short-lasting unilateral neuralgiform attacks with conjunctival injection and tearing (SUNCT)
	Hemicrania continua
	Cluster headaches
	Paroxysmal hemicrania
	Migraines

Question 57 of 280

□ □

A 75-year-old man is referred to you for the management of tremor and mobility issues. On examination, he has a noticeable resting tremor that is worse in the right hand when compared to the left. He also is quite bradykinetic when mobilising and displays mild rigidity. His speech and cognitive function do not appear to be affected. His blood pressure is 125/80 mmHg without any significant postural drop.

You suspect idiopathic Parkinson's disease. Further history taking reveals that this gentleman has had a previous significant gambling problem which is now well controlled.

Which of the following medications, in particular, should be avoided in this patient?

	Rasagiline
	Levodopa/carbidopa
	Pramipexole
	Entacapone
	Amantadine

□ Question 60 of 280

A 65-year-old man was referred to neurology outpatient clinic with a six month history of double vision. He had first noticed this when reading before going to bed but had more recently been occurring earlier during the day whenever the patient concentrated on an activity. The patient's wife also reported that she had been struggling to hear the patient when he spoke to her and that on several occasions the patient's eyelids had drooped during late in the day. The patient denied experiencing any weakness in his arms or legs but stated that his general mobility was normally very limited due to osteoarthritis of both his knees. Other past medical history included hypercholesterolaemia, hypertension and diverticular disease. Regular medications included bendroflumethiazide 2.5 mg OD, simvastatin 40 mg OD, co-dydramol as required. The patient was a retired builder and lived alone with his wife. He was an ex-smoker who rarely consumed alcohol.

Examination showed normal pupillary reflexes, visual acuity and visual fields. No ptosis was observed. Assessment of eye movements demonstrated a complex ophthalmoplegia with diplopia in all directions of gaze. There was significant weakness of bilateral facial muscles with bilateral involvement of the forehead. Examination of the tongue and palate was normal. Peripheral nerve examination was unremarkable except for evidence of fatiguable muscle weakness in the upper limbs.

Chest x-ray: clear lung fields with no effusion; no cardiomegaly; possible mediastinal widening

Haemoglobin	13.5 g / dL
White cell count	$8.9 \times 10^9/l$
Platelets	$409 \times 10^9/l$
Urea	4.7 mmol / L
Creatinine	95 micromol / L
Sodium	137 mmol / L
Potassium	4.8 mmol / L
Calcium (adjusted)	2.5 mmol / L

What is the single most sensitive investigation for the likely diagnosis?

	Repetitive nerve stimulation neurophysiology
	Serum acetylcholine receptor antibodies
	Serum muscle specific tyrosine kinase antibodies
	CT mediastinum
	Single fibre electromyography

□ Question 61 of 280

A 55 year old man presents to the Accident and Emergency department and a medical referral is requested. He reports that for the past week he has been hearing voices. He states that he cannot recognise who the voices are as they are whispering quietly but he thinks that they are making derogatory comments about him. He denies any visual hallucinations and you cannot illicit any delusional beliefs. His mood appears euthymic.

He tells you that he has a long history of alcohol dependence lasting for 30 years drinking approximately 10 units of alcohol a day on average. He tells you that in the past he has tried to stop drinking alcohol but this has caused admission to hospital due to seizures. He is particularly worried because he has cut down on alcohol since the hallucinations because he is worried that he is going mad. He is now only drinking 2 units a day and has not drunk any alcohol for 24 hours. On one previous occasion where he abstained from alcohol he said that he had hallucinations and had to be admitted to hospital for a few days and put on a drip and was told that he almost died.

Na ⁺	144 mmol/l
K ⁺	3.6 mmol/l
Urea	14.1 mmol/l
Creatinine	119 µmol/l

Bilirubin	36 µmol/l
ALP	199 u/l
ALT	92 u/l
γGT	271 u/l
Albumin	36 g/l

He has a family history of alcohol dependence and depression but no other psychiatric problems. His medications include Omeprazole, Vitamin B, Thiamine and Diazepam.

On examination his GCS is 15, there is no tremor or sweating Pulse 80 regular BP 138 / 74 chest clear, abdo soft non tender, no peripheral focal neurology MMSE 28/30 He is commenced on chlordiazepoxide and observed for 24 hours. His GCS remains at 15 and his repeat physical examination remains unchanged and the hallucinations are still present

What is the most likely diagnosis?

	Late onset schizophrenia
	Delerium tremens
	Alcohol withdrawal syndrome
	Alcoholic hallucinosis
	Hepatic encephalopathy grade 2

Dashboard

Overall score: 0%

Question 62 of 280

□ □

A 14-year-old presents to your neurology clinic reporting 9 months of subtle and gradual onset, progressive lower limb weakness. For the past 18 months, he has noticed a difficulty in keeping up with his peers in PE lessons, which he initially put down to 'not being very sporty'. However, he feels weak whenever he walks and has particular difficulty getting up from a chair.

On examination, you notice significantly hypertrophied calves on inspection. Formal examination of power reveals 4- out of 5 bilaterally in shoulder abduction, adduction and normal 5 out of 5 distally. 4- out of 5 is also noted in hip flexion and extension, 4+ in knee flexion and extension, 5 out of 5 in ankle plantar and dorsiflexion. The weaknesses demonstrated are not fatiguable and are persistent. Reflexes are present in all areas, plantars are downgoing. He has no other past medical history. His family history is unknown as he was adopted. What is the most likely diagnosis?

	Duchenne muscular dystrophy
	Becker muscular dystrophy
	McArdle syndrome
	Spinal muscular atrophy
	Inclusion body myositis

□ Question 65 of 280

□ □

A 65 year old lady was referred to the neurology clinic for assessment. She reported a 3 month history of progressive weakness. She had initially noticed difficulty opening jars, but reported that over the past month she had also had difficulty walking up stairs. She did not have any pain, and reported no changes in sensation. Past medical history included osteoporosis, type 2 diabetes mellitus and hypertension.

On neurological examination there were no fasciculations, tone was normal and sensation was intact. Power was reduced in finger flexion (3/5), wrist flexion (4/5), knee extension (3/5) and hip flexion (4/5) bilaterally. Other movements were relatively spared. Upper limb reflexes were present but diminished, but the knee jerk was absent. The plantar response was flexor bilaterally. There was no tenderness over any muscle groups. Cranial nerve examination was unremarkable.

Blood results are shown below:

Haemoglobin	122 g/l
White cell count	$8.2 \times 10^9/l$
Platelets	$376 \times 10^9/l$
C reactive protein	7 mg/l
Erythrocyte sedimentation rate	39 mm/hr
Creatine kinase	272 (24-170 U/l)

What is the most likely diagnosis?

	Diabetic amyotrophy
	Inclusion body myositis
	Motor neuron disease
	Myaesthesia gravis

She did not have any pain, and reported no changes in sensation. Past medical history included osteoporosis, type 2 diabetes mellitus and hypertension.

On neurological examination there were no fasciculations, tone was normal and sensation was intact. Power was reduced in finger flexion (3/5), wrist flexion (4/5), knee extension (3/5) and hip flexion (4/5) bilaterally. Other movements were relatively spared. Upper limb reflexes were present but diminished, but the knee jerk was absent. The plantar response was flexor bilaterally. There was no tenderness over any muscle groups. Cranial nerve examination was unremarkable.

Blood results are shown below:

Haemoglobin	122 g/l
White cell count	$8.2 \times 10^9/l$
Platelets	$376 \times 10^9/l$
C reactive protein	7 mg/l
Erythrocyte sedimentation rate	39 mm/hr
Creatine kinase	272 (24-170 U/l)

What is the most likely diagnosis?

	Diabetic amyotrophy
	Inclusion body myositis
	Motor neuron disease
	Myasthenia gravis

Question 66 of 280

A 45 year old Bangladeshi male presents with a 6 month history of bilateral reduced sensation on the tips of both his feet, which has gradually progressed on both legs to his low shins. His past medical history include type 2 diabetes, diagnosed 7 years ago and reports good medication compliance with metformin 500mg BD alone, with a HbA1c at 6.5mmol/l two weeks ago. He is also currently on his ninth month of anti-tuberculosis treatment, having initially presented with a chronic cough, night sweats and weight loss. An induced sputum subsequently cultured positive for acid fast bacilli. He did not bring in his medications but remembers being told they are 'the standard four then two drugs'. He takes no other medications and has no known drug allergies. On examination, tone, power and gait of his lower limbs are unremarkable. He demonstrates reduced sensation to light touch to his left lower-shin and right mid-shin. Ankle jerks are absent bilaterally, plantars are downgoing bilaterally. What is the most likely diagnosis?

	Guillain-Barre syndrome (GBS)
	Chronic inflammatory demylinating polyneuropathy (CIDP)
	Drug induced peripheral neuropathy
	Diabetic neuropathy
	Diabetic amyotrophy

Question 67 of 280

□ □

A 57 year old gentleman was brought to the emergency department by ambulance following a collapse 2 hours earlier. His partner witnessed him fall to the floor, and stated that he had not been moving his right arm and leg since. She said that he had been well before this episode. The ambulance crew reported that he had had a generalised tonic-clonic seizure, which was terminated after 6 minutes with 5mg of diazepam. On examination he was drowsy, with a Glasgow coma score of 10 out of 15, and his blood pressure was 165/92mmHg. He had a right sided facial droop and there was no movement in his right arm or leg. He was known to be a smoker, and he took amlodipine for hypertension. He was not on any other medications.

An urgent CT head scan was performed immediately which demonstrated loss of differentiation between the grey and white matter in the left frontal and parietal lobes, but no acute haemorrhage.

What is the most appropriate initial management?

	Aspirin 300mg for 2 weeks
	Intravenous alteplase 900 micrograms/kg
	Aspirin + dipyridamole 25/200mg
	Clopidogrel 75mg
	Warfarin

□ Question 70 of 280

A 58-year-old female is brought into hospital by her husband with recurrent falls associated with cognitive decline noted by her husband over the past 8 weeks. The patient's husband reports a possible cough and cold about 3 months ago, during which she took 2 days off work as a personal assistant to a FTSE 100 company CEO but otherwise has no significant past medical history, is a non-smoker and drinks minimal alcohol.

On examination, she is alert and orientated to time and place but appears easily startled every time you start a sentence. You note significant bilateral finger-nose and heel-shin dysmetria, mild postural tremor and mild speech slurring. The remainder of her neurological examination was unremarkable.

Her blood tests are as follows:

Hb	124 g/l
Platelets	$282 \times 10^9/l$
WBC	$4.8 \times 10^9/l$

Na ⁺	143 mmol/l
K ⁺	4.7 mmol/l
Urea	6.7 mmol/l
Creatinine	86 μ mol/l
CRP	3 mg/l
TSH	8.0 mu/l
Free T4	12.0 pmol/l
Anti-TPO	negative
HIV	negative
Glucose	6.5 mmol/l

A lumbar puncture was performed with results as follows:

WCC	<1 /mm ³
RBC	28 /mm ³
Protein	0.71 g/l
Glucose	3.4 mmol/l
Culture	no organisms grown
Viral PCR	awaited
Cytology	awaited
14-3-3	positive

An EEG demonstrated brief periodic spikes but these were not correlated with any seizure activity clinically. An MRI head demonstrated no parenchymal abnormalities except mildly increased signal in the cortical sulci.

What is the most likely diagnosis?

	Creutzfeldt-Jakob disease
	Viral encephalitis
	Acute disseminated encephalomyelitis (ADEM)
	Progressive multifocal leucoencephalopathy (PML)
	Hashimoto's encephalopathy

□ Question 73 of 280

A 43-year-old female presents with a second episode of loss of sensation in her left anterior thigh and right foot. This is her second episode within the past four months. She had recently reported an episode of left anterior shin numbness 1 year ago when an MRI with gadolinium demonstrated 'spots in her spinal cord' and she was diagnosed with transverse myelitis. Her past medical history also includes ulcerative colitis, diagnosed aged 27 years old and primary sclerosing cholangitis. Her serum tests are as follows:

Hb	125 g/l
Platelets	$274 \times 10^9/l$
WBC	$7.5 \times 10^9/l$

Na ⁺	139 mmol/l
K ⁺	4.4 mmol/l
Urea	4.7 mmol/l
Creatinine	78 μ mol/l
Bilirubin	49 μ mol/l
ALP	305 u/l
ALT	180 u/l

You commence five days of high dose oral methylprednisolone. What is the most appropriate next management?

	Interferon beta
	Glatiramer acetate
	Fingolimod

	Natalizumab
	Mitoxantrone

Question 74 of 280

A 78-year-old man is admitted following being found on the floor at home. He has no recollection of how he got to floor or how long he had been there. He reports feeling generally unwell and having a cough for a number of days. There is no medical history of note and he takes no regular medications. He lives alone and appears unkempt. Examination reveals bronchial breathing throughout his left mid zone. Neurologically, he has new onset weakness of left sided shoulder abduction and adduction, alongside mild weakness in left elbow flexion. Additionally, reduced sensation in the lateral aspect of his upper arm is noted. A CT head is undertaken.

CT head report	Age related involutional change. No evidence of intracranial haemorrhage or recent ischaemic event.
----------------	---

What is the most likely diagnosis?

	Stroke
	Rotator cuff tear
	Brachial plexus injury
	Brown-Sequard syndrome
	Botulism

Question 76 of 280

□ □

A 45-year-old lady has had weight loss over the last eight months. Over the last 3 months, she has become confused according to her family, forgetting things she would normally remember like telephone numbers or what she did during the day. She has now presented with a second episode of what sounds like a generalised tonic-clonic seizure in the last week. She has no other past medical history of note. Clinical examination shows MMSE of 23/30, cachexia, a bulky left adnexal region, and nil else. Routine blood tests are unremarkable. You organise a CT chest, abdomen, pelvis and head which reveal a suspicious lesion in the left ovary but are otherwise normal. You organise a biopsy of the left ovary, send off a paraneoplastic blood screen, and order an MRI of the brain. What would you expect the paraneoplastic screen to return showing?

	Voltage-gated potassium channel antibodies
	Anti-Hu antibodies
	Anti-GAD
	Anti-Ma2 antibodies
	NMDA receptor antibodies

Question 78 of 280

□ □

A 62 year-old man with a history of osteoarthritis, type II diabetes and mild dementia is seen in neurology clinic. He has a 2 month history of weakness in his right arm. He has also noticed that his voice has become softer. He is finding it hard to use door handles and open jars. On two occasions his wife has noticed him stumbling whilst walking.

On examination he has fasciculations over his right deltoid muscle and wasting of the interossei muscles of the right hand. There is 4/5 strength in right shoulder abduction on the Medical Research Council (MRC) scale. Limb reflexes are absent in the right arm but detectable elsewhere. Coordination is normal. Sensation is normal and Romberg's test is negative.

What is the most likely diagnosis?

	Compressive Cervical myelopathy
	Diabetic peripheral neuropathy
	Motor neurone disease
	Multiple sclerosis
	Thoracic outlet syndrome

Dashboard

Question 79 of 280

□ □

You are asked for advice on a 57 year old man who presented to primary care 12 weeks after an inferior myocardial infarction. He has had symptoms of persistent low mood that varies during the day, tearfulness and hopelessness. He has lost 6kg of weight in the past 3 months and his BMI is currently 19. He has fleeting thoughts of suicide but would not act on this as he does not want to hurt his family. You are told that 20 years ago, following an overdose of paracetamol, he was prescribed Citalopram and diagnosed with depression.

The GP tells you that other than the recent MI, he also has a diagnosis of Atrial Fibrillation, for which he is on warfarin and he has suffered from epigastric pain for the past 2 years. He had an OGD 1 year ago where treatment of a duodenal ulcer with adrenaline was required. Since then his symptoms of epigastric pain have decreased but are still present. There has been no repeat OGD.

What would be the safest course of action?

	Prescribe Phenelzine
	Prescribe Sertraline
	Prescribe Mirtazepine
	Prescribe Imipramine
	Refer for 2 month wait CBT

Dashboard

Question 80 of 280

□ □

You see a 46 year-old man who has been referred by his GP to the neurology clinic.

He gives a one year history of facial pain. The pain particularly comes on when he is shaving or brushing his teeth, and he describes it as 'stabbing' through the teeth of his upper jaw and over the left side of his face. He has seen a succession of dentists and had several teeth removed, with no relief. The pain has been getting progressively worse, and whereas before it occurred in discrete attacks, it now occurs almost all the time. He has read several online sources and has become convinced that he has a brain tumour, which has led to him becoming depressed and withdrawn.

His past medical history includes essential hypertension, for which he takes perindopril. He also suffers from sinusitis, and has had a sinus washout on more than one occasion. Two years ago whilst on a business trip abroad he had a problem with the vision in his right eye, which spontaneously resolved over a few weeks, and for which he sought no treatment.

General examination is unremarkable. Cranial nerve examination is largely normal but you notice that there is a patch of numbness over the left cheek. Power is 5/5 across all muscle groups in the limbs, reflexes are normal, and plantars are downgoing. Sensation in the limbs is normal.

What is the most appropriate course of action?

	Reassure him he has trigeminal neuralgia, for which unfortunately there is no treatment
	Reassure him he has trigeminal neuralgia, and start carbamazepine 300mg daily
	Refer to the neurosurgeons for microvascular decompression
	Perform MR head with gadolinium contrast
	Perform CT head with contrast

Overall score: **0%**

Question 80 of 280

□ □

You see a 46 year-old man who has been referred by his GP to the neurology clinic.

He gives a one year history of facial pain. The pain particularly comes on when he is shaving or brushing his teeth, and he describes it as 'stabbing' through the teeth of his upper jaw and over the left side of his face. He has seen a succession of dentists and had several teeth removed, with no relief. The pain has been getting progressively worse, and whereas before it occurred in discrete attacks, it now occurs almost all the time. He has read several online sources and has become convinced that he has a brain tumour, which has led to him becoming depressed and withdrawn.

His past medical history includes essential hypertension, for which he takes perindopril. He also suffers from sinusitis, and has had a sinus washout on more than one occasion. Two years ago whilst on a business trip abroad he had a problem with the vision in his right eye, which spontaneously resolved over a few weeks, and for which he sought no treatment.

General examination is unremarkable. Cranial nerve examination is largely normal but you notice that there is a patch of numbness over the left cheek. Power is 5/5 across all muscle groups in the limbs, reflexes are normal, and plantars are downgoing. Sensation in the limbs is normal.

What is the most appropriate course of action?

	Reassure him he has trigeminal neuralgia, for which unfortunately there is no treatment
	Reassure him he has trigeminal neuralgia, and start carbamazepine 300mg daily
	Refer to the neurosurgeons for microvascular decompression
	Perform MR head with gadolinium contrast
	Perform CT head with contrast

Question 81 of 280

□ □

A 73 year old female presents with a low frequency irregular tremor of the left hand and ataxia. The tremor is present at rest and when she holds her arms outstretched. The frequency of the tremor ranges from 3-4 Hz and is enhanced with posture and aggravated with movement. On neurological examination patient was found to have an ataxic gait with mild left arm weakness (power 4/5). She had a past medical history of type 2 diabetes mellitus, hypertension and previous stroke. What is the most likely diagnosis for her tremor?

	Essential tremor
	Holmes tremor
	Parkinsonian tremor
	Cerebellar tremor
	Physiological tremor

Question 82 of 280

A 16 year old boy is brought in to A&E by his mother after an episode of unresponsiveness while walking, lasting transiently for seconds before fully resolving. He has no recollection of these episodes. He was diagnosed with absence seizures aged 11 and was previously prescribed anti-epileptics. These had been gradually weaned off two years ago by his neurologists following a 3 year seizure-free period.

Over the past 48 hours, he has now had 4 of his typical absences. You decide to prescribe an anti-epileptic. Which anti-epileptic should you avoid?

	Carbamazepine
	Sodium valproate
	Lamotrigine
	Levetiracetam
	No contraindications

Question 83 of 280

A 28 year old female psychiatric nurse presents to the A+E department following a 2 minute tonic clonic generalised seizure, which self terminated. Whilst taking the history the following morning, she tells you that over the last 48 hours she has become increasingly unwell. She has been feeling increasingly anxious and has been having insomnia and vivid nightmares which wake her from sleep. She says that everything around her no longer looks real but more like a photocopy. Bowel and bladder movements have been normal. She feels generally weak and asks the lights to be dimmed in the examination room. When the nurse bell goes off in the next cubicle, she has to cover her ears.

On examination, she appears anxious, she is perspiring, respiratory rate 16/min, blood pressure 142/86 mmHg, heart rate 115 reg, sats 98% on air. You notice a fine tremor, especially in the hands and eyelids. GCS = 15. Oriented in time place and person. When you examine her, she tells you that it feels as if her legs are floating off the bed even though they are stationary. There is no flushing of the face

From looking at the computer records, you can see that she has a history of panic disorder treated with PRN lorazepam and sertraline 1 year ago. and has been treated for depression in the past. You also note from your records that she presented to A+E 5 days ago due to stress as she was sacked from her job.

Hb	13.6 g/dl
Platelets	232 * 10 ⁹ /l
WBC	6.9 * 10 ⁹ /l

Na ⁺	142 mmol/l
K ⁺	3.8 mmol/l
Urea	6.2 mmol/l
Creatinine	81 µmol/l

What is the most likely diagnosis?

	Benzodiazepine withdrawal
	Atypical Panic attack secondary to panic disorder
	LSD intoxication
	Benzodiazepine excess
	Opiate withdrawal

□ Question 84 of 280

A 77 year old male presents to the Emergency Department with a two day history of right temporal, throbbing headache, constant in nature and 8/10 severity. He report this being the first ever episode of this headache and is different to his previous migraines, which have been typically on the left occipital region, lasting minutes, and fairly stereotyped over the past 60 years. Apart from migraines, he has no other medical history. On examination, his right scalp is tender and a prominent right temporal artery is noted. He is afebrile with no skin rashes. His blood tests are as follows:

Hb	13.8 g/dl
Platelets	$552 \times 10^9/l$
WBC	$11.5 \times 10^9/l$
ESR	85 mm/hr

Na ⁺	146 mmol/l
K ⁺	4.4 mmol/l
Urea	9.6 mmol/l
Creatinine	115 μ mol/l
CRP	23 mg/l

You empirically start him on 60mg prednisolone. He undergoes temporal artery biopsy within 24 hours of his admission demonstrating no signs of temporal arteritis.

What is the most appropriate next step?

	Repeat temporal artery biopsy
	Continue prednisolone but at reduced dose 10mg OD
	Discharge

	Continue prednisolone at 60mg
	Start anti-migraine medication

□ Question 85 of 280

□ □

A 42-year-old woman attends neurology clinic for review of her treatment strategy for multiple sclerosis. The patient had first developed symptoms of multiple sclerosis five years previously. Her first episode had involved sensory loss and motor weakness affecting her left leg. An MRI brain scan conducted at this time had demonstrated multiple lesions suggestive of multiple sclerosis. At this point in time, the patient had decided against receiving disease modifying therapy.

One year after her first episode, the patient suffered an episode of optic neuritis. A repeat MRI scan had demonstrated a progression of the previously observed radiographic lesions. Subsequently, the patient had been initiated on treatment with interferon beta. This treatment was continued for two years during which time the patient suffered no further relapses of multiple sclerosis. However, the patient found the unwanted effects of interferon beta to be progressively harder to tolerate and she eventually decided against continuing with this treatment. A subsequent trial of glatiramer acetate was quickly halted due to the patient experiencing severe symptoms of flushing.

Following the cessation of disease-modifying therapy, the patient had experienced multiple further relapses, including one episode where she had required hospitalisation due to cranial nerve involvement. Further assessment during this period found that the patient met the local criteria for aggressive or highly active multiple sclerosis. Accordingly, later line therapies were discussed with the patient who was keen to proceed.

Aside from her history of multiple sclerosis the patient suffered from no other significant medical problems and took no regular medications. The patient was a science teacher that had been unable to work for the past year due to her multiple relapses.

The later line therapy recommended for the patient is natalizumab. What is the essential investigation that must be completed prior to initiation of treatment with natalizumab?

	Transthoracic echocardiogram
	JCV antibody status
	Pulmonary function tests
	Thyroid function tests

□ □

An 83-year-old female presents to the emergency department. The patient describes a vague history of arm and leg weakness and loss of vision though is unsure of a particular limb or visual field distribution. She states that these symptoms seemed to last around 6 hours. There are no abnormalities noted in the upper and lower neurological examination nor cranial nerve examination in the emergency department. The patient has a history of regular migraine of around 2 a week for the last 20 years, type two diabetes mellitus treated with metformin and hypertension which was diagnosed 8 years ago currently treated with amlodipine.

Her observations are.

Blood pressure - 145/90 mmHg

Heart rate - 83 beats per minute

Temperature - 37.5C

Respiratory rate - 15

Oxygen saturation - 98% on air

You suspect the patient may have had a transient ischaemic attack. Which radiological investigation is the most appropriate to aid diagnosis at this stage?

	MRI head with fluid attenuation inversion recovery (FLAIR)
	CT head with contrast
	Carotid dopplers
	MRI head
	MRI head with diffusion weighted imaging

□ Question 89 of 280

A 27-year-old man attends ambulatory care with a one day history of facial droop. He is a mountain bike instructor and is extremely anxious that this may be related to a fall last month. He hasn't been riding for the last month because he has felt unwell with aches and pains and some odd bruising up his leg.

On examination he has a bilateral VII nerve weakness but no other cranial nerve lesions detected. The arms and legs show no focal neurology.

Skin is intact with no skin lesions seen. There is no evidence of any joint effusions and all joints appear to have a full range of motion

Investigations:

Haemoglobin	127 g/L (130-180)
White cell count	10.0 × 10 ⁹ /L (4.0-11.0)

Chest X-ray	Normal
-------------	--------

What is the most likely diagnosis?

	Sarcoidosis
	Lymes Disease
	Syphilis
	Bells Palsy
	Subdural Haemorrhage

Dopaminergic neuron of the substantia nigra

□ Question 94 of 280

A 66-year-old female is brought into Emergency Department by her distraught husband, who reports that she has not been out of bed for 3 days and seems unable to recognise him. He reports no recent fevers or rigors, she has not complained of cough, dysuria, sore throat or diarrhoea and vomiting prior to being unwell. She is well known to local neurologists: she is undergoing off-label rituximab for difficult to manage relapsing-remitting progressive multiple sclerosis, with previous white matter lesions in her corpus callosum, periventricular white matter, and lower thoracic transverse myelitis.

Over the past 6 years, she had continued to relapse despite interferon beta, natalizumab, mitoxantrone and cyclophosphamide. At baseline, she is weak in her lower limbs and is able to stand only with assistance of a turning apparatus, then able to walk about 3 steps. She is normally cognitively intact and fully orientated, normally responsible for organising the couples finances. Her past medical history includes type 1 diabetes mellitus, autoimmune thyroiditis and previous deep vein thrombosis 5 years ago (warfarin since discontinued). Her medication history includes lantus, novomix, levothyroxine and 3 monthly infusions of rituximab, which had stably maintained her MS for 4 years.

On examination, she is not orientated to time or place and appears extremely irritable. Halfway through the examination, she becomes extremely tearful. There is a full range of neck movements and no photophobia.

Neurological examination is difficult due to patient cooperation: pupils are equal and reactive, there is a full range of eye movements and no obvious facial asymmetry. Power in her upper limbs were at least 3/5, lower limbs are unable to counteract gravity. Both plantar responses are upgoing. Her bloods are as follows:

Hb	134 g/l
Platelets	$268 \times 10^9/l$
WBC	$7.8 \times 10^9/l$

Na ⁺	137 mmol/l
K ⁺	4.4 mmol/l
Urea	4.5 mmol/l
Creatinine	60 μ mol/l

CRP	5 mg/l
HIV	negative
Glucose	7.4 mmol/l

A lumbar puncture was performed:

WBC	16 /mm ³
RBC	150 /mm ³
Protein	0.71 g/l
Glucose	3.5 mmol/l
PCR and gram staining	awaited

What is the most appropriate management step?

<input type="radio"/>	Intravenous aciclovir
<input type="radio"/>	Intravenous methylprednisolone
<input type="radio"/>	Intravenous immunoglobulin
<input type="radio"/>	Intravenous rituximab infusion
<input type="radio"/>	Psychiatric input

□ Question 94 of 280

A 66-year-old female is brought into Emergency Department by her distraught husband, who reports that she has not been out of bed for 3 days and seems unable to recognise him. He reports no recent fevers or rigors, she has not complained of cough, dysuria, sore throat or diarrhoea and vomiting prior to being unwell. She is well known to local neurologists: she is undergoing off-label rituximab for difficult to manage relapsing-remitting progressive multiple sclerosis, with previous white matter lesions in her corpus callosum, periventricular white matter, and lower thoracic transverse myelitis.

Over the past 6 years, she had continued to relapse despite interferon beta, natalizumab, mitoxantrone and cyclophosphamide. At baseline, she is weak in her lower limbs and is able to stand only with assistance of a turning apparatus, then able to walk about 3 steps. She is normally cognitively intact and fully orientated, normally responsible for organising the couples finances. Her past medical history includes type 1 diabetes mellitus, autoimmune thyroiditis and previous deep vein thrombosis 5 years ago (warfarin since discontinued). Her medication history includes lantus, novomix, levothyroxine and 3 monthly infusions of rituximab, which had stably maintained her MS for 4 years.

On examination, she is not orientated to time or place and appears extremely irritable. Halfway through the examination, she becomes extremely tearful. There is a full range of neck movements and no photophobia.

Neurological examination is difficult due to patient cooperation: pupils are equal and reactive, there is a full range of eye movements and no obvious facial asymmetry. Power in her upper limbs were at least 3/5, lower limbs are unable to counteract gravity. Both plantar responses are upgoing. Her bloods are as follows:

Hb	134 g/l
Platelets	$268 \times 10^9/l$
WBC	$7.8 \times 10^9/l$

Na ⁺	137 mmol/l
K ⁺	4.4 mmol/l
Urea	4.5 mmol/l
Creatinine	60 μ mol/l

CRP	5 mg/l
HIV	negative
Glucose	7.4 mmol/l

A lumbar puncture was performed:

WBC	16 /mm ³
RBC	150 /mm ³
Protein	0.71 g/l
Glucose	3.5 mmol/l
PCR and gram staining	awaited

What is the most appropriate management step?

	Intravenous aciclovir
	Intravenous methylprednisolone
	Intravenous immunoglobulin
	Intravenous rituximab infusion
	Psychiatric input

Question 95 of 280

A 79-year-old is brought into hospital with muscle cramps, fevers and passing dark urine. He is known to have previously had Parkinson's disease and takes Sinemet 125 five times a day. His daughter, who normally picks up his medicine for him from the pharmacy has been called away on business for the past 5 days. As a result, the patient's supplies ran out and he has not taken his PD meds for 3 days. His blood pressure is fluctuant, from 77/52 mmHg to 150/88mm Hg. On examination, his temperature is 39.2 degrees, his heart sounds are quiet but present and chest auscultation is unremarkable. You note rigid muscles in four all limbs, no obvious superficial evidence of head injury and new confusion, with abbreviated mental test 0/10. You start intravenous fluids, intravenous broad spectrum antibiotics, catheterise the patient and insert a nasogastric tube to administer his regular medications. What is the underlying diagnosis?

	Urosepsis
	Restrictive pericarditis
	Idiopathic Parkinson's disease progression
	L-dopa dyskinesia
	Neuroleptic malignant syndrome

Question 96 of 280

A 23-year-old student presented with a tremor in his right arm. He had also noticed increasing difficulty with speech, clumsiness in both hands and unsteadiness walking. He reported being very stressed and anxious. His relationship with his long-term girlfriend had come to an end and his younger brother had recently been diagnosed with bipolar affective disorder.

This student had a past medical history of depression and was born prematurely at 29 weeks gestation requiring ventilatory support in the neonatal intensive care unit. He took no regular medications and denied recreational drug use. He was, however, a binge drinker, consuming at least 30 units of alcohol per week. He had a penicillin allergy.

On examination there was a bilateral resting tremor more marked in the right arm than the left. The tone of the right arm was slightly increased. The movements of his upper limbs and hands were slow with reduced dexterity although there was no weakness. Reflexes were present and symmetrical. There was no sensory disturbance. On walking this patient had a broad-based, slow, ataxic gait with small steps. Rombergs test was negative. Power, tone, reflexes and sensation in the lower limbs were normal.

Investigations:

Hb	11.0 g/dl
Platelets	$110 \times 10^9/l$
WBC	$10.5 \times 10^9/l$
International Normalised Ratio	1.3

Na ⁺	134 mmol/l
K ⁺	4.0 mmol/l
Urea	5.8 mmol/l
Creatinine	78 μ mol/l

--	--

Bilirubin	80 µmol/l
ALP	211 u/l
ALT	94 u/l
Amylase	72 u/l

Given the most likely underlying diagnosis which of the following would be the most appropriate management plan?

	Start penicillamine as an inpatient and prescribe an alcohol detoxification regimen
	Prescribe an alcohol detoxification regimen and refer to a geneticist
	Start pentoxifylline and prescribe an alcohol detoxification regimen
	Start trientine as an inpatient and prescribe an alcohol detoxification regimen
	Refer to the psychiatric team

□ Question 97 of 280

A 64 year old man presented to the Emergency Department after becoming unwell at home. His wife reported that the patient experienced a sudden onset and severe headache while watching television. Shortly afterwards she found him to have become confused and drowsy and an ambulance was called. On arrival in the Emergency Department, the patient suffered a witnessed tonic-clonic seizure, self-terminating after two minutes.

The patient had known hypertension and hypercholesterolaemia and had suffered a non-ST elevation myocardial infarction two years before, treated with a drug-eluting stent to the left anterior descending artery. Regular medications included ramipril 10 mg OD, bisoprolol 10 mg OD, bendroflumethiazide 2.5 mg OD, simvastatin 40 mg OD and aspirin 75 mg OD. The patient's wife reported that compliance with anti-hypertensive medications had been inconsistent and that controlling the patient's blood pressure had been an on-going problem over the previous two years. The patient was a retired builder and ex-smoker.

On examination, the patient was drowsy (GCS M4V2E3) but was protecting his own airway. Pupils were equal and reactive. The patient was spontaneously moving all his limbs and had downgoing plantar reflexes. Cardiovascular, respiratory and abdominal examination was unremarkable. Initial observations and investigations are listed below.

Blood pressure 220 / 115 mmHg

Heart rate 89 beat / minute

O2 sats (15 L O2) 100 %

Respiratory rate 19 / minute

Temperature 37.1°C.

CT brain: no extra-axial bleeding or collection; no intracerebral haemorrhage; no evidence acute ischaemic stroke; no subarachnoid blood; normal ventricular system; mild small vessel disease in keeping with patient's age.

Lumbar puncture:

CSF red cells	3/ mm ³
CSF white cells	3 / mm ³
CSF gram stain	unremarkable
CSF glucose	60 % serum level

protein	0.5 g / L
CSF	negative for bilirubin and xanthochromia

Given persistent reduced GCS and need to obtain blood pressure control, patient was intubated and transferred to the neuro intensive care unit. Following discussion with neurological team further imaging was arranged

MR brain with angiography: structurally normal brain as per previous study; bilateral symmetric vasogenic oedema involving the subcortical white matter in the parietal-occipital, posterior temporal and posterior frontal lobes; MRA unremarkable without any area of stenosis or vasospasm.

What is the correct diagnosis?

<input type="checkbox"/>	Reversible cerebral vasoconstriction syndrome
<input type="checkbox"/>	Posterior reversible leucoencephalopathy syndrome
<input type="checkbox"/>	Acute disseminated encephalomyelitis
<input type="checkbox"/>	Cerebral venous thrombosis
<input type="checkbox"/>	Pituitary apoplexy

□ Question 98 of 280

□ □

A 26-year-old man is admitted for investigation after having increasing trouble walking. On admission he is found to have a severely ataxic gait and is unable to walk in a straight-line. For many weeks he has been complaining of visual problems, dizziness, headaches and clumsiness.

On examination he is noted to have horizontal nystagmus, an intention tremor and past pointing. On fundoscopy a large, erythematous retinal lesion is present surrounded by tortuous, dilated vessels.

His father had similar problems in his 20's.

A CT scan is arranged:

□ Question 99 of 280

A 36-year-old male from India presents with worsening headache and vomiting. He is known to have HIV but has been lost to follow up over the last 5 years. His CD4 count from his last appointment was 400.

On examination he has no localising signs however fundoscopy revealed papilloedema.

Investigations:

haemoglobin	115 g/L (115-165)
white cell count	$9.4 \times 10^9/L$ (4.0-11.0)
platelet count	$220 \times 10^9/L$ (150-400)
erythrocyte sedimentation rate	50 mm/1st h (<30)
serum urea	7.0 mmol/L (2.5-7.0)
serum creatinine	105 mol/L (60-110)
serum alanine aminotransferase	17 U/L (5-35)
serum aspartate aminotransferase	26 U/L (1-31)
Cryptococcal antigen test	Negative
CD4 Count	65 cells/mm ³
CT Head	5cm ring enhancing lesion in right temporal lesion with surrounding oedema

What is most appropriate management?

	Amphotericin, Fluconazole and prednisolone
	Rifampicin, Isoniazid, Pyrazinamide, Ethambutol and prednisolone

	Trimethorpim-Sulphamethoxazole, Rifampicin, Isoniazid, Pyrazinamide, Ethambutol and prednisolone
	Start prednisolone but defer treatment until lumbar puncture performed

□ Question 101 of 280

A 64 year old man presents with a 6 month history of abnormal behaviours which have been noticed by his wife. He has described seeing vivid visual hallucinations of clowns in his living room which sometimes talk to him and appear very real. He believes that he is the head of a circus and is about to go on a world tour although this is not true.

At times he is lucid and is fully independent but at other times he is disorientated in time and place and is unable to perform simple tasks such as preparing food and going to the shops. His wife thinks that his mood is also lower since the onset of symptoms. He presented in A+E today because of having a second fall in two weeks.

There is no history of infective symptoms. He went to see his GP two days ago who thought that he may have a UTI and prescribed trimethoprim.

He has a history of stroke 10 years ago and hypertension and takes warfarin, amlodipine and enalapril.

Physical examination is unremarkable except for slightly increased tone on the left side compared to the right.

Bloods:

Hb	14.9 g/dl
Platelets	$387 \times 10^9/l$
WBC	$12.8 \times 10^9/l$

Na ⁺	142 mmol/l
K ⁺	4.6 mmol/l
Urea	6.4 mmol/l
Creatinine	84 μ mol/l

Bilirubin	6 μ mol/l
ALP	64 u/l

ALT	15 u/l
Calcium	2.35 mmol/l
Albumin	41 g/l

MSU (from GP from 2 days ago): Heavy growth of E.coli Sensitive to trimethoprim, nitrofurantoin, amoxicillin and co-amoxiclav

CT Brain: some generalised atrophy and periventricular white matter changes normal for age. Changes in keeping with an old left sided lacunar infarct

Mini Mental State Examination 17/30

Which medications would most appropriately treat the underlying diagnosis?

	Olanzapine
	Rivastigmine
	Co-amoxiclav
	Sinemet
	Aspirin 300mg

A 75-year-old right handed female with a background of breast cancer treated with chemotherapy five months ago presents with a two day history of difficulty finding her words. There is no history of seizure or headache. On examination she has a Glasgow coma scale 15/15, she is a pyrexial, there is no dysarthria, although there is an apparent expressive dysphasia with no other focal neurology. Her blood tests are unremarkable.

Her CT head is reported as follows:

Left inferior frontal lesion with surrounding oedema consistent with a metastasis

What is the next most appropriate step?

	Intravenous dexamethasone
	Lamotrigine
	Mannitol
	Intravenous aciclovir
	Loading dose of phenytoin

□ Question 107 of 280

A 60-year-old man presents with a few hours history of severe left sided headache, described as a sharp pain behind the eye and around the temple. When his scalp is touched it elicits severe pain. He describes a transient loss of vision in the left eye that lasted for seconds during the onset of the pain. He has been feeling unwell with fevers and intermittent headaches for the past week. 2 years ago he had been diagnosed with cluster headaches and has had them intermittently, the last attack was 3 months ago.

On examination his scalp was tender to touch, and a prominent temporal artery could be felt. The temperature was 37.9°C, heart rate 90bpm, respiratory rate 22 breaths per minute, saturating 100% on air. Pupils were equal and reactive to light, no photophobia. no diplopia or ophthalmoplegia on eye movements. Rest of cranial nerve examination was normal. Fundoscopy revealed no evidence of papilloedema.

Na+	137mmol/l
K+	4.3 mmol/l
Urea	5.7 mmol/l
Creatinine	67 µmol/l
Serum glucose	5.8 mmol/l
C Reactive protein (CRP)	78mg/l
Erythrocyte Sedimentation Rate (ESR)	Awaiting results.
Haemoglobin	156 g/l
White cell count	10.2 x 10 ⁹ /L
INR	1.0

What is the next appropriate management step?

	CT Head scan
	Intravenous normal saline

	15L oxygen via a non re-breather mask
	Prednisolone 60mg orally
	200mg Ibuprofen

Dashboard

Overall score: 0%

Question 111 of 280

□ □

A 75-year-old female on aspirin for known ischaemic heart disease is being investigated for the cause of a recent transient ischaemic attack (TIA) which caused brief left sided weakness. She does not have a history of atrial fibrillation, nor has any been detected on routine telemetry.

Her MRI brain scan does not provide any evidence for acute stroke and her transthoracic echocardiogram does not demonstrate any intra-cardiac thrombus.

A carotid ultrasound study revealed a 75-85% stenosis of the right internal carotid artery. In addition to ordering a CT carotid angiogram to further investigate the lesion, the next best step in her management would be to?

	Add clopidogrel
	Commence best medical management and re-image in 6 months
	Commence an unfractionated heparin infusion
	Commence best medical therapy and refer for a carotid endarterectomy in 6-8 weeks
	Commence best medical therapy and refer for a carotid endarterectomy within 14 days

Dashboard

□ Question 112 of 280

□ □

A 79-year-old woman is admitted to the Emergency Department via an ambulance after being found in an unresponsive, drowsy state. Her daughter phoned her earlier in the day routinely. At this point she complained of a headache. Upon arriving at her mother's house she found her confused and lying on the floor.

On examination her GCS is 9/15 (M4V3E2), pulse 96/min and blood pressure 140/78 mmHg.

A CT head is arranged:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Epidural haematoma
	Subdural haematoma
	Subarachnoid haemorrhage
	Sagittal sinus thrombosis
	Cavernous sinus thrombosis

A 54-year-old man presents with neck pain and feeling generally unwell. This has been getting progressively worse over the past two weeks and is now 'unbearable'. He feels hot and also complains of headaches.

He emigrated from Pakistan 30 years ago. He smokes 20 cigarettes/day and does not drink alcohol.

On examination pulse is 102/min, blood pressure 124/74 mmHg and temperature 37.9°C. He has weakness in both arms

MRI of his cervical spine is shown below:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Cervical disc prolapse
	Syringomyelia
	Cervical epidural abscess
	Meningitis
	Tuberculosis

□ Question 114 of 280

□ □

An 88-year-old woman is brought in by her daughter as her memory has been deteriorating over the past year. Upon clarification with her daughter, it is confirmed that the patient has deteriorated over many months and has not had an acute illness. She has no significant past medical history apart from an appendicectomy when she was a teenager. On examination, the patient is comfortable at rest, has a temperature of 36.8 degrees Celcius, heart rate of 70 beats per minute and blood pressure of 115/90mmHg. What should be included in her initial screen apart from haematology and biochemistry?

	Thyroid function tests, and serum B12 and folate
	Thyroid function tests, serum B12 and folate, syphilis, and HIV
	Thyroid function tests, serum B12 and folate, lumbar puncture, midstream urine

Question 115 of 280

□ □

A 72-year-old male presents to the Parkinson's clinic with his wife, reporting increasing frequency and duration of 'off' periods. The couple finds these episodes extremely debilitating and occurs up to 11 times a day. The patient was diagnosed with Parkinson's disease 12 years ago. As a relatively young patient on diagnosis, he was commenced on ropinirole, which he continued for 5 years, before being prescribed Sinemet 6 times a day and entacapone for the following 7 years. Over past 2 years, the 'off' episodes have gradually increased in frequency in addition to the development of very mild involuntary jaw movements. He is very low in mood and has presented to the emergency department with two episodes of attempted paracetamol overdoses. He would like a more effective treatment. What would you recommend?

	Deep brain stimulation
	Subcutaneous apomorphine
	Reintroduce ropinirole at higher doses
	Palliative care involvement
	Trihexyl

Dopaminergic neuron of the substantia nigra

□ Question 116 of 280

A 25 year old man presents to A+E in a comatose state. He was found by his university flatmate collapsed on the floor. His flatmate states that the man had been behaving bizarrely in the last 24 hours and had been quite agitated and aggressive at times. When you examine him he has a GCS of 8 (E 2 V 1 M 5). He has a temp of 39.4°C, heart rate 120/min, blood pressure 178/89 mmHg, sats 98% on room air and respiratory rate 20/min. Chest clear abdomen soft and non-tender, bowel sounds present. Globally greatly increased tone in all 4 limbs.

When looking at his previous electronic notes the only information that you can find is a recent admission to a psychiatric hospital where a diagnosis of paranoid schizophrenia was established.

CT Brain: normal

Hb	15.4 g/dl
Platelets	232 * 10 ⁹ /l
WBC	11.5 * 10 ⁹ /l

Na ⁺	143 mmol/l
K ⁺	4.1 mmol/l
Urea	8.1 mmol/l
Creatinine	101 µmol/l

Bilirubin	14 µmol/l
ALP	63 u/l
ALT	28 u/l
Calcium	2.64 mmol/l
Albumin	41 g/l
Creatine kinase	21,000 iu/l

Serum glucose	6.4 mmol/l

Question 118 of 280

□ □

A 45 year old man develops weakness of the extensors in the wrist and digits of his left upper limb over a week. Over the next 2 months he also notices weakness of the small muscles of hands on the right side, and that he is progressively unable to dorsiflex his right foot. On examination, he has wasting and 2/5 power in the left wrist and digit extensors. On the right he has clawing of the right ring and little fingers along with wasting of the small muscles of the hand on that side (except the thenar eminence and the first two lumbricals, which are spared). He has a right foot drop along with wasting of the anterior tibial and perineal muscles on that side. Fasciculations are seen in all of the areas of weakness. Sensory examination and reflexes are normal, along with no clonus. Plantars are down-going. The remainder of the examination are normal. Nerve conduction studies show conduction block. What is first-line maintenance treatment for this condition?

	Riluzole
	Intravenous immunoglobulin
	Pyridostigmine
	Steroids
	Beta-interferon

Question 119 of 280

□ □

An 81-year-old lady with a history of congestive cardiac failure was assessed in accident and emergency and clinically diagnosed with an acute ischaemic stroke. Her main deficits were slurred speech and left sided facial droop with some loss of fine motor control in the left hand. On admission, her blood pressure was 185/70mmHg with a heart rate of 95 beats per minute in sinus rhythm.

The initial CT scan of her brain showed some evidence of chronic small vessel ischaemia, but no acute pathology, in particular no haemorrhage was seen. Which of the following combinations of investigations should be carried out during the acute admission?

	MRI, transthoracic echocardiogram (TTE), cardiac telemetry and carotid duplex study
	Transoesophageal echocardiogram (TOE), CT cerebral angiogram and carotid duplex study
	CT scan, fasting lipids and a video fluoroscopy swallow study
	Fasting glucose, Electroencephalogram (EEG), MRI and thrombophilia screen
	Thrombophilia screen, MRI and a TTE

□ Question 120 of 280

□ □

A 53-year-old lady was admitted to the medical admission unit having presented to the Emergency Department with a severe headache which had developed over the last five days. She described the headache as a continual dull pain across the front of her head and was significantly worsened when she sat up as well as when she coughed or strained. It was alleviated only when she lied down in a dark room; paracetamol 1g QDS and ibuprofen 400mg TDS did not provide any relief. She denied the presence of nausea or vomiting, her vision was not affected and other than feeling tired she did not complain of any other symptoms. Her past medical history was comprised of non-classical migraines and hypothyroidism for which she was prescribed levothyroxine 175mcg OD. Seven days ago she was admitted with a headache, fever and photophobia; review of her medical notes revealed the following results from the previous admission:

Hb	142 g/l
Platelets	$326 \times 10^9/l$
WBC	$11.2 \times 10^9/l$

Glucose	5.4 mmol/l
ESR	32 mm/hr
CRP	46 mg/l
PTT	12.2 (NR 12-14s)
APTT	44s (NR 300-46s)
Fibrinogen	5.2 (NR 2-4 g/l)

Urine MCS: NAD

Blood MCS: NAD

CT Head: normal intracranial appearances; no space occupying lesion or haemorrhage identified

Lumbar puncture:

Protein	0.3g (NR 0.2-0.4 g/L)
Glucose	3.6 mmol/l
WCC	8 (<5/mm ³)
Opening pressure	15 (NR 10-20 cmH ₂ O)
MCS	NAD

Examination revealed the presence of a female in a dark room lying flat. Her temperature was 36.6°C, heart rate 77bpm, respiratory rate 16/min and blood pressure 136/78 mmHg. Examination her cardiovascular and respiratory systems were unremarkable. Examination of her neurological system revealed the presence of normal functioning cranial nerves 2-12 with unremarkable fundoscopy; there was no neck stiffness or photophobia objectively. There was no neck stiffness and Kernig's sign was negative. Examination of her peripheral neurological system was unremarkable.

What is the single next best management option?

<input type="radio"/>	Organise urgent cranial MR venogram scan
<input type="radio"/>	Organise urgent cranial MRI scan
<input type="radio"/>	Commence therapy with sumatriptan
<input type="radio"/>	Administer epidural blood patch
<input type="radio"/>	Send CSF for xanthochromia analysis

□ Question 122 of 280

□ □

An 85 year old woman was referred by her General Practitioner to the stroke team on an urgent outpatient basis after her rest home staff reported a unusual episode the previous week. The patient normally suffered from mild dementia but was independent with activities of daily life with minimal assistance from care staff. One week previously, she had been found unusually drowsy in an armchair at her home. Staff recalled that she had been inconsistent with following commands and in particular was unable to raise her left arm in the air and was unable to stand. The drowsiness and arm weakness had resolved within 30 minutes, however the patient had subsequently been more confused than normal with reduced mobility. On direct questioning, rest home staff than a few days prior to the above episode the patient had lost her balance and had sat down heavily on the ground. The care worker with her at the time was certain that the patient had not hit her head during this incident.

Past medical history included mild dementia, myocardial infarction and atrial fibrillation. Regular medications included aspirin 75 mg daily, ramipril 2.5 mg daily, bisoprolol 2.5 mg daily, simvastatin 20 mg daily and warfarin (target INR 2-3). Review of recent blood test monitoring showed that the patients INR had been well controlled over recent months with no results outside of the therapeutic range. The patient did not drink and was a long-term ex-smoker. As mentioned above, the patient normally needed minimal assistance with self-care and was fully continent.

Examination in clinic demonstrated a significant cognitive impairment (abbreviated mental test score 4/10) but without evidence of dysphasia. Pupils were equal and reactive to light with no papilloedema on fundoscopy. There was a full range of conjugate eye movements. No facial weakness or sensory loss was demonstrated. Tongue and palate function was unremarkable with no weakness of trapezius muscle. Examination of the peripheral nerves was unremarkable except for possible slight pronator drift in the left arm and an up going left plantar response. Cardiovascular examination was unremarkable except for an irregular pulse. Respiratory and abdominal examination was unremarkable.

Results of investigations performed at the time of clinic assessment are given below.

Electrocardiogram: atrial fibrillation at rate 80 bpm, normal axis, inferior T wave inversion

Chest x-ray: clear lung fields

Carotid doppler: no significant stenosis in right internal carotid artery; 50 % stenosis in left internal carotid

Transthoracic echocardiogram: mild left ventricular systolic impairment, normal valvular function, no mural thrombus

What is most likely finding on CT brain scan performed after clinic review?

	Sub-arachnoid haemorrhage
	Cerebral infarction
	Intracerebral haemorrhage
	Normal pressure hydrocephalus
	Sub-dural haematoma

Dashboard

Chest x-ray: clear lung fields

Carotid doppler: no significant stenosis in right internal carotid artery; 50 % stenosis in left internal carotid

Transthoracic echocardiogram: mild left ventricular systolic impairment, normal valvular function, no mural thrombus

What is most likely finding on CT brain scan performed after clinic review?

	Sub-arachnoid haemorrhage
	Cerebral infarction
	Intracerebral haemorrhage
	Normal pressure hydrocephalus
	Sub-dural haematoma

Question 123 of 280

□ □

A 56 year-old consultant surgeon has recently been diagnosed with idiopathic Parkinson's disease, and attends clinic for review.

You read the previous clinic letter and see that he presented with tremor affecting mainly the right hand, which forced him to stop operating. On examination he also had some bradykinesia and rigidity of the right hand. He was started on co-beneldopa 100/25, initially one tablet three times daily, with instructions to up-titrate as tolerated.

When you see him today, he is concerned that there has been no improvement in the tremor. This is causing him considerable distress as he hopes to return to clinical work. His motor control is otherwise good, and throughout the day and night he has no difficulty with 'off' periods or freezing. He currently takes co-beneldopa 100/25, two tablets three times daily, and reports no complications.

On examination there is a resting tremor of the right hand. There is no discernable rigidity or bradykinesia.

What is the best treatment option?

	Increase dose of co-beneldopa
	Increase frequency of co-beneldopa
	Add procyclidine
	Add entacapone
	Add selegiline

□ Question 126 of 280

A 45-year-old lady was admitted to the Medical Admission Unit with a 16-hour history of weakness. Two days prior to the admission she experienced a sensation of double vision and shortly afterwards had become more unsteady when walking. The weakness developed initially in her arms and was shortly followed by weakness in her legs. Her past medical history included a history of coeliac disease for which she adhered to a strict gluten-free diet, but she was otherwise fit and well.

On examination, she was not distressed and was fully orientated to her surroundings. She had a temperature of 37.6°C, a heart rate of 88/min, a respiratory rate of 18/min and a blood pressure of 182/82 mmHg. The cardiovascular and respiratory examination was otherwise unremarkable. Examination of the abdomen revealed a mass arising from the symphysis pubis. Examination of her cranial nerves revealed a failure of bilateral external gaze, as well as diplopia on asking the patient to fixate down and in. Her pupils were dilated but reactive. Fundoscopy revealed no abnormalities, and cranial nerve examination was otherwise unremarkable. The tone was reduced in all muscle groups, with a power of grade 3/5 in all muscle groups. Reflexes were absent in all limbs and plantar responses were normal. She was unable to mobilise independently and an ataxia was noted.

Initial investigations revealed the following:

Hb	132 g/l
Platelets	222 * 10 ⁹ /l
WBC	5.8 * 10 ⁹ /l
ESR	16 mm/hr

Na ⁺	139 mmol/l
K ⁺	3.7 mmol/l
Urea	4.3 mmol/l
Creatinine	77 µmol/l
Bilirubin	11 µmol/l
ALP	101 u/l

ALT	22 u/l
Glucose	6.0 mmol/l
CRP	22 mg/l

Appearance	Clear
Glucose	4.5 mmol/l
Protein	0.6 g/l
White cells	3 / mm ³

CT brain scan: normal appearances, no evidence of haemorrhage, midline shift or space occupying lesion.

What is the single investigation most likely to lead to a diagnosis?

<input type="radio"/>	Anti Jo1 antibodies
<input type="radio"/>	Anticholinesterase antibodies
<input type="radio"/>	Anti GQ1b antibodies
<input type="radio"/>	Anti GM1 antibodies
<input type="radio"/>	Antinuclear antibodies

Question 127 of 280

A 42 year old male presents with double vision and weakness in his fingers, which he noticed when he repeated dropped his pen when trying to write at work. His symptoms appear to have onset over the past few days. He has no past medical history other than a recent episode of diarrhoea and vomiting about two weeks ago. He reports no limb weakness and no sensory loss. He denies any back pain or palpitations. On examination, there is a 3/5 weakness in finger flexion, finger extension and wrist extension in both hands, with no fatiguability. No reflexes present in the lower or upper limbs. There is no ptosis or nystagmus but reduced eye movements in all directions. His finger-nose test demonstrates reduced coordination bilaterally and the patient has too little confidence to walk. Which investigation is diagnostic?

	Anti-GM1 antibody
	Anti-GQ1b antibody
	MRI brain and whole spine
	Anti-MUSK (muscle specific kinase) antibody
	Anti-acetylcholine receptor antibody

□ Question 129 of 280

A 36 year old male presents to your outpatient clinic with a progressive history over the past 5 years of increasing, progressive 'clumsiness'. His work colleagues had a long running joke with him that he is poorly coordinated for about the past five years but in recent weeks, he has noticed that he is unable to write legibly or even hold a key still using either hand to open a door. He denies any recent weight loss or night sweats, is otherwise healthy with no other past medical history. He is a lifelong non-smoker with a minimal alcohol history and lives with his wife and 2 children.

On examination, his cranial nerves were unremarkable except for mild multidirectional nystagmus at primary gaze. Fundoscopy was normal. Limb examination revealed significant impairment of finger-nose and heel-shin testing. His gait, tone, power, sensation and reflexes were normal with downgoing plantars. A brief mini-mental state examination scored 30/30. An MRI head is awaited. His blood tests are as below:

Hb	15.8 g/dl
Platelets	$323 \times 10^9/l$
WBC	$6.5 \times 10^9/l$

Na ⁺	141 mmol/l
K ⁺	4.9 mmol/l
Urea	6.6 mmol/l
Creatinine	85 μ mol/l
CRP	2 mg/l
Creatine kinase	223 IU/l (50-335)
TSH	3.3 mu/l
Free T4	17 nmol/l
HIV	negative
Anti-neuronal antibodies	negative

Which investigation is likely to yield the diagnosis?

	Neurogenetics testing
	CT chest, abdomen, pelvis
	Vitamin B12 and folate levels
	Lumbar puncture for cerebrospinal fluid including 14-3-3 and S100
	Anti-GQ1b antibodies

Dashboard

Question 130 of 280

□ □

A 69-year-old male presenting with a 4-month history of progressive 'droopiness' of his left eyelid. He reports that in the last 2 weeks, he has been unable to lift his eyelid at all, which he says is fortunate considering he gets double vision now when he lifts his eyelid with his fingers. He underwent a renal transplant in 1988, which continues to function well, and previously had a squamous cell and malignant melanoma resected 2 and 5 years ago respectively.

On examination, you note complete ptosis, loss of vertical eye movements and loss of adduction in his left eye. On head tilt to the right, he is unable to depress left eye. His right eye demonstrates full eye movements. The left pupil is unreactive and larger in diameter compared to the right. There is also loss of sensation at the left nasal skin fold and left forehead with sparing of his left chin. He has no facial weakness, hearing loss or palatal asymmetry. He denies headache or retroorbital pain.

Where is the likely lesion?

	Left ocular neuromuscular junction
	Left cavernous sinus
	Left superior orbital fissure
	Cerebral aqueduct
	Left midbrain

Dashboard

Overall score: 0%

□ Question 132 of 280

A 70-year-old male is evaluated at the neurology outpatient department for an episode of left sided body weakness which lasted for around 30 minutes and resolved completely. He described the episode as an inability to move the left side of his body and an associated numbness and tingling sensation in the area involved. He remained conscious throughout and was able to communicate verbally with his family members during the episode.

He suffers from hypertension and has hypercholesterolaemia. He is also a smoker with a 40 pack year history and is known to be a heavy drinker.

He has also noted a tremor in both his hands which tends to improve after he has a drink. He also feels unsteady while walking and feels the need to grip something otherwise he may lose balance. His medication includes amlodipine 5mg daily and atorvastatin 20mg daily.

On examination, his blood pressure is 150/95mmHg and his pulse is 86bpm regular. A carotid bruit is audible over both sides of the neck. Neurological examination reveals impaired sensations in a glove and stocking distribution. The remaining clinical examination is normal.

Investigations reveal:

ECG: deep S waves in lead V1-V3 and tall R waves in V4-V6

CXR: Enlarged cardiac silhouette with flecks of calcification around the aorta

Carotid artery Doppler studies reveal 85% occlusion in the right external carotid. 50% occlusion in the right internal carotid. Left internal carotid is 80% occluded while there is a 60% occlusion in the left external carotid artery.

Which of the following is the most suitable treatment option in this patient?

	Left internal carotid endarterectomy
	Optimizing medical management
	Right external carotid endarterectomy
	Percutaneous stenting of the right internal carotid artery

Dashboard

Overall score: **0%**

□ Question 133 of 280

A 63-year-old man presented with a three-week history of double vision and fatigue. Over this period he had noticed that when he swallowed liquids these often came back out of his nose. He reported a decreased exercise tolerance over the past six months due to fatigue and shortness of breath.

On examination he was thin. He had bilateral ptosis and diplopia on looking in multiple directions. His voice was soft and he appeared peripherally cyanosed. On auscultation his chest was clear and heart sounds were normal.

Observations:

- Heart rate: 90 beats per minute
- SaO₂: 92% on room air
- Respiratory rate: 22 breaths per minute
- Temperature: 37.1 degrees Celsius
- Blood pressure: 110/68 mmHg

Arterial blood gases breathing air:

PO ₂	7.80 kPa (11.3 12.6)
PCO ₂	9.52 kPa (4.7 6.0)
pH	7.31 (7.35 7.45)
bicarbonate	32.4 mmol/L (21 29)
base excess	10 mmol/L (+/- 2)

Which urgent investigation should be performed next?

	Chest X-ray
	Forced vital capacity
	Computed Tomography Pulmonary Angiogram

	Electrocardiogram
	Bedside echocardiogram

Dashboard

Question 134 of 280

□ □

A 59-year-old woman is referred by her GP to neurology clinic for assessment. The patient describes intermittent episodes of pain affecting the left side of her face. She recalls the first attack vividly as a sudden onset of severe 'electric-shock' pain coming on suddenly around one year previously as she had cleaned her teeth with her electric toothbrush. The pain was felt around the cheek extending down to the jaw-line. The first attack had lasted several hours and she had ultimately attended her dentist and received a filling to a left molar tooth. While symptoms from that episode had resolved, she had then suffered from similar episodes at increasing frequency, approximately every fortnight over the last couple of months. These attacks had on occasion been unprovoked but were sometimes induced by stimulation of the affected area or cold winds. The patient was tearful as she recounted the negative impact her symptoms had had on her lifestyle. There was no history of headaches, sinus symptoms or seizures.

The patient had a fairly unremarkable past-medical history, notable only for hypothyroidism and long-standing struggles to avoid overweight. Her only regular medication was thyroxine 125 micrograms daily and the patient reported no allergies. There was no family history of neurological disease. The patient worked as a law clerk and did not smoke or drink significant alcohol.

Examination demonstrated an unremarkable cranial nerve and peripheral nerve examinations. In particular, colour vision, visual acuity and hearing were normal.

What is the correct first line management of the patient's symptoms?

	Gabapentin
	Carbamazepine
	Pregabalin
	Baclofen
	Lamotrigine

Overall score: **0%**

Question 135 of 280

□ □

An 84-year-old male presents as a blue light ambulance call with a twelve hour history of sudden onset inability to move his right side. On examination, you note an expressive and receptive dysphasia associated with a dense right sensori-motor syndrome. Cardiovascular examination was unremarkable except for an irregular heartbeat at 80 per minute. A hyperacute CT head demonstrated a large area of ischaemia in the left middle cerebral artery vascular territory. The patient was outside the window for thrombolysis and started on 300mg aspirin. Subsequent echocardiogram demonstrated 60% ejection fraction with no mural thrombus, 40% left and 35% right stenosis on carotid Doppler while a 24hr tape demonstrated new atrial fibrillation. How can the risk of subsequent strokes be reduced?

	Subcutaneous low molecular heparin at 48 hours after stroke
	Warfarinisation at 48 hours after stroke
	Warfarinisation at 14 days after stroke
	Referral to vascular surgery for left carotid endarectomy
	Insertion of permanent pacemaker

□ Question 136 of 280

As the medical registrar on-call you are fast-bleeped to see a patient in the resuscitation room of the Emergency Department.

A 27 year-old lady presented with severe breathing difficulties and hypoxia, and had become increasingly drowsy whilst in the department. Arterial blood gases performed by the emergency physicians showed:

pH	7.142
pCO ₂	12.5 kPa
pO ₂	9.19 kPa
HCO ₃	25.3 mmol/l

Due to the rapidity of her decline, the emergency physicians tell you that only a very brief history was possible before she required intubation. She described a productive cough over the last few days, and mentioned that she was taking tablets for a neurological condition.

On examination, she is intubated and maintained on sedation with propofol. You notice a well-healed midline sternotomy scar. On auscultation of the chest there are coarse crackles audible in the left mid and lower zones.

She is transferred to the Intensive Care Unit for continued mechanical ventilation and is commenced on empirical broad-spectrum antibiotics.

Which one of the following additional interventions will most hasten her recovery?

	Botulinum anti-toxin
	Edrophonium
	Plasma exchange
	3,4-diaminopyridine

Dashboard

Question 137 of 280

□ □

An 80-year-old lady is seen in the Emergency Department following a fall at home. She states she tripped over a rug whilst carrying her tea into the living room. She did not hit her head or lose consciousness. She fell onto her right hip and was unable to get up due to pain. She was found by her daughter two hours later.

She has a past history of high blood pressure (for which she takes amlodipine and ramipril) and osteoarthritis. She lives alone and is independent aside from her daughter bringing her shopping. She walks with a stick out of doors.

On examination she is alert and oriented. She has a large bruise over her right hip and a small skin tear on her right arm. Her heart rate is 96 beats per minute and her blood pressure is 110/56 mmHg. Systems examination is normal.

X-rays of her hips and pelvis show osteoarthritic change but no fractures.

She is unable to mobilise with the physiotherapist in the emergency department and is admitted to the ward overnight.

In the early hours of the following morning, she becomes confused and agitated. She is shouting that burglars are trying to steal her belongings. She is not oriented in place or time.

Which tool should be used to assess this lady's mental state?

	4AT
	Abbreviated Mental Test Score (AMTS)
	Confusion Assessment Method (CAM)
	Mini Mental State Examination (MMSE)
	Montreal Cognitive Assessment (MoCA)

Overall score: **0%**

□ Question 139 of 280

A 47 year old female with relapsing-remitting multiple sclerosis (MS) describes increasing difficulty with fatigue, and has had to give up her work as a medical secretary. She has always been careful about ensuring a balanced diet, gentle exercise and early treatment of infection. On review and questioning her mood is good. Her most recent bloods are shown below:

Hb	120g/dl
Platelets	$150 \times 10^9/l$
WBC	$5.2 \times 10^9/l$

Na	130 mmol/l
K	3.8 mmol/l
Urea	6.0 mmol/l
Creatinine	68 μ mol/l

B12, folate and TFTs are normal.

What is the best course of action?

	Advise that she increase caffeine intake
	Advise that increasing exercise may benefit
	Trial of vitamin D
	Trial of amantadine
	Trial of ropinirole

Dashboard

Question 140 of 280

□ □

A 21-year-old Caucasian female presents to eye casualty with an episode of sudden onset blurred vision in her left eye. She reports noticing it about 10 days ago and reports progressive deterioration associated with pain on eye movement until her presentation today. There is a vague history of a possible 'cough and cold' about 3 weeks ago but she has reported no other recent illnesses. She has no past medical history, is on the oral contraceptive pill and has no other medications. There is no smoking, alcohol or recreational drug history.

On examination, you note visual acuity and colour vision on Ishihara plates to be 6/6 and 17/17 plates in her right eye, 6/24 and 0/17 plates in her left eye. A left relative afferent papillary defect was demonstrated, fundoscopy was unremarkable. Examination of her other cranial nerves and limbs were unremarkable. Her blood tests were unremarkable and she has declined a lumbar puncture. An MRI head and whole spine demonstrates no abnormalities except for a swollen left optic nerve is visualised. What is the most appropriate treatment?

	No treatment, reassure patient vision will resolve
	Oral prednisolone
	Intravenous methylprednisolone
	Intravenous immunoglobulin
	Interferon beta

□ Question 142 of 280

A 25-year-old woman presents to the neurology outpatient clinic with a month history of worsening headache.

The headache is mostly frontal in nature but does move to the back of her head sometimes. It never goes away but is worst in the morning. It is throbbing in nature. In the last week it has begun to make her feel sick, although she has not vomited. She has also developed a thudding sound in her ears which she first noticed when trying to go to sleep at night but now sometimes hears at other times. She has no change in her vision or photophobia.

She has no past medical history of note and has no allergies. Her only current medication is the oral contraceptive pill. She is obese, drinks no alcohol and smokes ten cigarettes per day.

On examination her heart rate is 90/min and her blood pressure is 165/94 mmHg. Her pupils are equal and reactive and her visual fields are full to confrontation. Vision is 6/6 in both eyes and extra-ocular movements are normal. Fundoscopy reveals slight blurring of the optic disc margins with a normal retina.

Examination of the other cranial nerves reveals no deficits. On examination of the upper and lower limbs, tone, power, coordination and reflexes are all normal, with downgoing planters. Her BMI is 31.

Blood tests:

Hb	150 g/l
Platelets	$250 \times 10^9/l$
WBC	$7 \times 10^9/l$

Na ⁺	136 mmol/l
K ⁺	4 mmol/l
Urea	6 mmol/l
Creatinine	72 μ mol/l

What is the next most appropriate imaging investigation?

	CT angiogram head
	CT head without contrast
	MR angiogram head
	MRI head without contrast
	MR venogram head

Dashboard

□ Question 143 of 280

□ □

A 64 year old man is referred to you from a psychiatrist for a second opinion. He initially presented with a 3 month history of low mood, apathy and suicidal ideation. In addition he was asked to retire early from his job as an accountant as he was performing poorly at work. He is also sleeping an average of 14 hours per day.

When the psychiatrist assessed him he noted abnormal jerky movements in the lower limbs as well as a broad based gait. An MMSE was performed and he scored 15/30. This is corroborated by your examination and you also note hyperreflexia in the lower limbs and nystagmus.

He has no history of cognitive impairment or any psychiatric history. There is no family history of any neurological or psychiatric conditions and his only past medical history is an appendectomy 20 years ago which was complicated by a large intraperitoneal bleed.

Which findings are you most likely to find on investigation?

	Increased T2 and FLAIR signal intensity in the putamen and head of the caudate on T2 weighted MRI, 14-3-3 protein on CSF
	CAG trinucleotide repeats on the short arm of chromosome 4
	Increased T2 and FLAIR signal intensity in the putamen and head of caudate on T2 weighted MRI and oligoclonal bands on CSF
	CAG trinucleotide repeats on the short arm of chromosome 12
	Cortical atrophy, most prominent in the frontal lobes

Question 144 of 280

□ □

A 45 year old previously fit and well man presents to the emergency department with worsening leg weakness. He is in full time employment as a brick layer and is normally very active. Over the last 24 hours he has started dragging his feet and feels unsteady when walking, describing his gait 'like a drunk man'. On questioning he also describes increasing difficulty passing urine and has not had the sensation to empty his bladder for the past eight hours. He denies any preceding trauma, recent viral illness or similar previous symptoms in the past.

On examination he has normal muscle bulk and no fasciculations. There is symmetrical lower limb flaccid paralysis to the hips, with symmetrical hyporeflexia. He has a sensory level to T10 and is in urinary retention. Examination of the upper limbs and cranial nerves is entirely normal.

Which of the following would be the most useful initial investigation?

	Aquaporin 4 antibodies
	Lumbar puncture
	MRI spinal cord
	MRI brain
	HIV serology

Dashboard

□ Question 145 of 280

□ □

A 55-year-old woman attends neurology clinic for follow-up. At her first appointment 6 months previously, a clinical diagnosis of trigeminal neuralgia had been made and treatment with carbamazepine initiated. During clinic review the patient complained of ongoing symptoms with only limited benefit from drug treatment.

On her previous assessment, the patient had reported pain episodes associated with the cheek and jaw of the right side of her face. Subsequently, in addition to similar ongoing episodes, the patient had suffered from two episodes of pain affecting the forehead and peri-orbital region on the left side of her face. On one occasion, she had suffered from both right and left sided pain at the same time. She reported that the carbamazepine treatment had initially reduced the intensity of the pain episodes by perhaps 50 %, but that the severity of recent attacks had again worsened to their original level. When her drug history was checked, it was apparent that the carbamazepine dose had been titrated up appropriately by the patients GP.

The patient also stated that following her previous clinic appointment she had been discussing the situation with her sister, who had reminded the patient that their mother had suffered several episodes of visual loss during her life but had not undergone any medical investigation.

Cranial nerve examination demonstrated normal eye movements and pupillary responses. There was no evidence of facial nerve weakness, however a subjective numbness of sensation was noted in the left cheek region (this had not been noted on previous examination in clinic). There were no lesions around the head and neck or inside the mouth. Peripheral neurological examination was remarkable for borderline dysdiadochokinesia in the right upper limb and a positive Babinski response in the right lower limb.

What is the most appropriate investigation for this patient?

	Visual evoked potentials
	Three-plane fine-slice MRI brain with contrast
	CSF oligoclonal bands
	CT brain with contrast
	Standard protocol MRI brain with contrast

Dashboard

Overall score: **0%**

□ Question 146 of 280

A 24 year-old university student presents with a 10 day history of visual disturbance. He reports changes in his visual acuity where he has been experienced some blurring of his vision which is considerably worse after having been for a run. He thinks it is related to some pain he developed on his right eye prior to the onset of his vision loss. He has no previous history of visual problems and is normally fit and well. He takes no regular medications.

On further questioning he reports that 6 months ago he had some sensory changes on his lower limbs. He felt they were numb and this persisted for a few weeks. He thought it was due to his sporting activities, as he is an avid hockey player.

He drinks 20 units of alcohol at the weekends and does not smoke.

His blood results are shown below:

Hb	134 g/l
Platelets	250 * 10 ⁹ /l
WBC	8 * 10 ⁹ /l
Na ⁺	134 mmol/l
K ⁺	4.1 mmol/l
Urea	4 mmol/l
Creatinine	60 µmol/l

Which investigation below would be most useful to diagnose this patient?

	EEG
	CT head
	HIV serology
	Contrast MRI brain and spine

	Anti-NMO antibodies

A 24 year-old university student presents with a 10 day history of visual disturbance. He reports changes in his visual acuity where he has been experienced some blurring of his vision which is considerably worse after having been for a run. He thinks it is related to some pain he developed on his right eye prior to the onset of his vision loss. He has no previous history of visual problems and is normally fit and well. He takes no regular medications.

On further questioning he reports that 6 months ago he had some sensory changes on his lower limbs. He felt they were numb and this persisted for a few weeks. He thought it was due to his sporting activities, as he is an avid hockey player.

He drinks 20 units of alcohol at the weekends and does not smoke.

His blood results are shown below:

Hb	134 g/l
Platelets	$250 \times 10^9/l$
WBC	$8 \times 10^9/l$
Na ⁺	134 mmol/l
K ⁺	4.1 mmol/l
Urea	4 mmol/l
Creatinine	60 μ mol/l

Which investigation below would be most useful to diagnose this patient?

EEG
CT head
HIV serology
Contrast MRI brain and spine

□ Question 147 of 280

A 72 year old male from Dominican Republic presents with a 4 month history of constant bilateral anterior thigh pain and lower limb weakness, starting first in the left before progressing to bilateral symptoms. He reports being an extremely active man prior to these symptoms, continually to work as a landscape gardener until four months ago, and now he is wheelchair and bed-bound. He denies any history of trauma to his hips, previous tuberculosis infection or contact with heavy metals. His thigh pain appears excruciating, described as burning in nature along the anterior aspects of both thighs to the origin of the patella tendon bilaterally. He reports no recent weight loss, pyrexia or skin changes. His past medical history includes hypertension, hypercholesterolaemia, hypothyroidism and type 2 diabetes mellitus (diagnosed 6 years ago).

On examination, the patient has mildly reduced muscle bulk in bilateral hip flexors and bilateral fasciculations in both thighs. Examination of power demonstrates 2+/5 bilaterally in hip flexion 4+/5 hip extension bilaterally and 5/5 all other lower limb movements. Sensory examination revealed reduced sensation to cotton wool in both thighs and distal feet, reduced proprioception in both toes. Reflexes were 2+ at both knee jerks, absent ankle jerks bilaterally and downgoing plantars bilaterally. His blood tests are as follows:

Hb	13.4 g/dl
Platelets	383 * 10 ⁹ /l
WBC	4.5 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	4.6 mmol/l
Urea	8.6 mmol/l
Creatinine	112 µmol/l
CRP	1 mg/l
Creatine kinase	116 IU/l (50-335)
HbA1c	68 mmol/mol
TSH	2.1 mu/l

Free T4	15.4 nmol/l
---------	-------------

A MRI scan was performed of his lumbosacral plexus, demonstrating no appreciable structural lesion. Nerve conduction studies and EMG are awaited.

What is the optimal treatment?

	Optimise diabetic control
	Riluzole
	Intravenous immunoglobulin
	Intravenous methylprednisolone
	Lumbar puncture

Question 148 of 280

□ □

You have been referred a 45-year-old man by the Accident and Emergency doctors with a severe headache. The headache woke him up at 3am, and he describes it as the worst headache he's ever had, (although he admits he's not a regular headache sufferer). He has had seven episodes like this over the past two weeks that have followed a very similar pattern, with the other two headaches lasting around 60 minutes before going. The pain is mainly around the left eye and temple and is sharp in nature. You have to ask him to sit down to examine him because he is up and pacing around his room, clearly very agitated. On examining him you note that his left eye is watering and swollen, and there's some redness and mild bruising just above the eye. When you ask him about this bruising he says that the pain was so bad he bashed his head against the fridge door to try and help take it away.

On examination he has normal power, sensation and reflexes in all four limbs.

On examining his cranial nerves you notice that he has a mild left sided ptosis and miosis, and there is conjunctival injection and lacrimation on that side too.

His neck movements are slow but complete, and he has no obvious stiffness or photophobia

What is the most likely cause of his headache?

	Cluster headache
	Subarachnoid haemorrhage
	Paroxysmal hemicrania
	Migraine
	Tension headache

Question 149 of 280

□ □

A 76 year old residential home resident was seen in the neurology clinic. She had a history of Alzheimer's disease, and her behaviour had become progressively more challenging over the past 4 months, for which she had been started on regular haloperidol.

The residential home staff had reported that over the previous four weeks she had developed involuntary movements of her mouth, with frequent tongue protrusion and lip-smacking. There were no neurological deficits, and no history of blackouts. Two weeks ago she was reviewed by the general practitioner who stopped her haloperidol. However, her involuntary facial movements became more prominent following this.

On examination she appeared well, other than continuous involuntary lip-smacking, tongue protrusion, and frequent eye-blinking. She was alert, and there were no focal neurological deficits.

What is the most likely cause for her symptoms?

	Temporal lobe epilepsy
	Progression of Alzheimer's disease
	Chronic tardive dyskinesia
	Frontotemporal dementia
	Huntington's disease

Question 150 of 280

A 76 year old male is referred by the GP to your Parkinsons disease clinic. The patient and his wife described an increasing frequency of falls, the most frightening of which occurred when he fell 4 steps down a flight of stairs last week, luckily with no lasting damage. On examination, you note a slow pill rolling tremor equally on both hands and bilateral cog-wheeling. His cranial nerves are unremarkable except a poverty of upwards gaze. His speech appears distinct and nasal in character. What is the diagnosis?

<input type="checkbox"/>	Idiopathic Parkinsons disease
<input type="checkbox"/>	Vascular Parkinsonism
<input type="checkbox"/>	Progressive supranuclear palsy (PSP)
<input type="checkbox"/>	Multi-system atrophy (MSA)
<input type="checkbox"/>	Corticobasal degeneration (CBD)

□ Question 151 of 280

A 28-year-old woman presents with a gradually worsening headache, nausea and vomiting.

The headache started about 3 days ago coming on over about 3-4 hours and is worse on coughing and lying flat. She has been complaining of some nausea and vomiting which she had attributed to some reheated curry she had the night before.

She is usually fit and well but did suffer a spontaneous below-knee deep vein thrombosis (DVT) 3 years ago which was treated with warfarin for 6 months. She has been taking over-the-counter paracetamol and ibuprofen for the headache and currently has a Mirena intrauterine coil in-situ for contraception. She has no known drug allergies.

She currently works as a sales associate. She smokes 10 cigarettes a day and drink 21 units of alcohol a week.

On examination she looks unwell, pale and nauseated. Her blood pressure was 140/98 mmHg, heart rate 100 bpm, oxygen saturations of 98% on air. Her temperature was 36.1 degrees Celsius.

Heart sounds were normal, and her calves soft and non-tender with no evidence of thromboembolism.

Her chest was clear and her abdominal examination was unremarkable.

On neurological examination there was no cranial nerve abnormalities noted. She had normal tone, power, reflexes and sensation in both her upper and lower limbs. Coordination was intact.

Bloods taken by the Emergency Department were as follows:

Na+	136 mmol/L
K+	3.9 mmol/L
Urea	4.8 mmol/L
Creatinine	76 µmol/L
Hb	12.5 g/dL
WBC	11.0 x 10 ⁹ /L

Platelets	350 x 10 ⁹ /L
INR	0.9
aPTT	30 seconds
LFTs	Normal

CT head was performed and reported as normal.

Following this a lumbar puncture was performed:

CSF colour	Clear
Opening pressure	250 mmH ₂ O
White cell count	5.0 x 10 ⁶ /L (all lymphocytes)
Red cell count	15 x 10 ⁶ /L
Protein	0.3 g/L
Glucose	4.4mmol/L (Serum glucose 5.3mmol/L)

What is the most likely diagnosis?

<input type="checkbox"/>	Intracranial venous thrombosis
<input type="checkbox"/>	Subarachnoid haemorrhage
<input type="checkbox"/>	Migraine
<input type="checkbox"/>	Intracerebral malignancy
<input type="checkbox"/>	Subdural empyema

Question 152 of 280

□ □

A 58 year old man presents to Accident and Emergency with his wife complaining of memory loss. His first noticed a problem when he had difficulty making breakfast in the morning. When you question him, he has no memory of the events of today and patchy memory of the events of the past week although his wife informs you that he had no problem with his memory yesterday. He appears extremely anxious about his memory loss and repeatedly asks you 'Have I got dementia?'. He is able to remember his name and date of birth and recognise and name his wife. However, when using the toilet, he becomes lost and is unable to find his way back to the cubicle.

On examination his HS 1 + 2 + 0, he has corneal arcus, chest is clear. There is reduced power 4/5 to all arm movements in the right arm with normal reflexes, tone and sensation. His wife tells you that this has been present for several years following a stroke. There is no facial droop, there is no dysarthric speech or any other peripheral focal neurology and there are no cerebellar signs. Gait is normal.

He is able to count back from 20-1 and can name objects you present to him without difficulty. However he scores 0/3 on the delayed recall section of the MMSE. He is alert and fully responsive throughout the consultation.

Past medical history is of previous left sided middle cerebral territory infarct and one previous TIA one year ago. Hypercholesterolemia, hypertension. He has a 20 pack year history of smoking and used to drink 4-6 units of alcohol per day for 20 years but stopped this 25 years ago and his wife corroborates this information. His medications include Clopidogrel, Atorvastatin, Ramipril and Bendroflumethiazide.

CT Brain was performed 3 hours after waking up and is consistent with an old left sided infarct. No other abnormality detected.

What is the most appropriate treatment for this diagnosis?

	Intravenous thiamine and Vitamin B
	Oral thiamine and vitamin B
	Thrombolysis
	Donepezil

Dashboard

Overall score: **0%**

□ □

A 55-year-old male is found confused on street by a policeman. Hospital records document that he is a known to be a type 2 diabetic with previously DNAs to clinic and known poor compliance with medications. He also had two previous admissions to hospital, 2 and 10 years ago, for alcohol withdrawal. On examination, the patient is not orientated in time or place, scoring 0 out of 10 on abbreviated mental. He is able to follow your commands in lifting his upper and lower limbs during his neurological exams. All reflexes were present. He fails to follow your finger with his eyes on cranial nerve examination. His gait is grossly ataxic, as you noted when he tried to walk to the toilet against medical and nursing advice. His blood sugar is awaited. What is the diagnosis?

	Wernicke's encephalopathy
	Delirium
	Miller-Fisher syndrome
	Hypoglycaemia secondary to anti-glycaemic overdose
	Acute ischaemic stroke

Dashboard

Relationship between Wernicke's encephalopathy and Korsakoff's syndrome

Wernicke's encephalopathy

- nystagmus
- ophthalmoplegia
- ataxia

if untreated

Korsakoff's syndrome

- amnesia (antero + retrograde)
- confabulation

i.e. initially

↳ Wernicke's encephalopathy
if not treated with thiamine
↳ Wernicke-Korsakoff syndrome

Question 154 of 280

□ □

A 76-year-old gentleman with diabetes mellitus was referred to a specialist memory clinic by his family doctor. His wife was concerned as he had been more forgetful recently and had developed urinary incontinence. His family doctor had treated him with a course of trimethoprim for a urinary tract infection but his symptoms had persisted.

On examination this gentleman smelt strongly of urine. He had a broad-based, unsteady gait. Examination of his cardiovascular and respiratory systems was unremarkable but on abdominal examination there was suprapubic tenderness. He was orientated to place but scored only 22/30 on a Mini Mental State Examination (MMSE).

Urinalysis:

Blood -
Protein Trace
Nitrites -
White cells +
Microscopy 50 white cells seen, bacteria +
Cultures Mixed growth, please send repeat sample

Magnetic Resonance Imaging (MRI) of the brain: 'Disproportionately enlarged ventricular system compared with the degree of sulcal atrophy.'

Lumbar Puncture (LP):

Opening pressure	18 cmH ₂ O (12 20)
Appearance	Clear and colourless
Red cells	4
White cells	1 (0 5)
Gram stain	No organisms seen
Culture	No organisms seen
Protein	30 mg/100ml (15 60)

Glucose	98mg/100ml (50 80)
Virology	No viruses detected on PCR
Cytology	No abnormal cells seen
Timed 10 metre walk pre-LP	15 seconds
Timed 10 metre walk post-40 mL CSF drainage	12 seconds

Given the underlying diagnosis what is the definitive treatment of choice?

	Repeated therapeutic lumbar punctures
	Acetazolamide
	Referral for a ventriculo-peritoneal shunt
	Vitamin B12 and folate replacement
	Referral for lumbar drain insertion

□ Question 155 of 280

A 42 year-old man presents with an acute onset of weakness in the left face, arm, and leg, which has not resolved. On examination there is upper motor neuron facial weakness on the left, with dense weakness of the left arm and leg. There is no evidence of sensory neglect, hemianopia, or dysphasia.

He past medical history includes migraine with visual aura, for which he takes propranolol and sumatriptan. His last migraine attack was a month ago. He has suffered two transient ischaemic attacks in the last year, and now also takes clopidogrel. His father also suffered from migraine with aura and died in his 50s after suffering a series of strokes.

Plain computed tomography shows multiple round lesions in the white matter, which appear the same density as cerebrospinal fluid. Magnetic resonance imaging shows scattered well-circumscribed lesions in the subcortical white matter which appear hypointense on T1 and hyperintense on T2-weighted sequences. On DWI (diffusion-weighted imaging) there is a hyperintense lesion in the right internal capsule, with a corresponding hypointense area on the ADC (apparent diffusion coefficient) map.

What is the most likely underlying diagnosis?

	Patent foramen ovale
	Progressive multifocal leukoencephalopathy
	Migrainous infarction
	Cerebral amyloid angiopathy
	CADASIL

Question 155 of 280

□ □

A 42 year-old man presents with an acute onset of weakness in the left face, arm, and leg, which has not resolved. On examination there is upper motor neuron facial weakness on the left, with dense weakness of the left arm and leg. There is no evidence of sensory neglect, hemianopia, or dysphasia.

He past medical history includes migraine with visual aura, for which he takes propranolol and sumatriptan. His last migraine attack was a month ago. He has suffered two transient ischaemic attacks in the last year, and now also takes clopidogrel. His father also suffered from migraine with aura and died in his 50s after suffering a series of strokes.

Plain computed tomography shows multiple round lesions in the white matter, which appear the same density as cerebrospinal fluid. Magnetic resonance imaging shows scattered well-circumscribed lesions in the subcortical white matter which appear hypointense on T1 and hyperintense on T2-weighted sequences. On DWI (diffusion-weighted imaging) there is a hyperintense lesion in the right internal capsule, with a corresponding hypointense area on the ADC (apparent diffusion coefficient) map.

Question 156 of 280

□ □

An 80-year-old male presents to the Parkinson's disease (PD) clinic complaining of jerking and flailing movements of his arm. He says he has no control of them and finds them embarrassing and disabling. However, he reports very few other PD symptoms, with minimal problems with 'off' periods. His past medical history includes PD, diagnosed 8 years ago, and type 2 diabetes. He currently takes Sinemet 250 for Parkinson's disease 5 times a day and metformin 500mg TDS, he has been on the same dose of Sinemet for past 18 months. What is your most appropriate management?

	Reduce dose of Sinemet
	Increase dose of Sinemet
	Start entacapone
	Start ropinirole
	Deep brain stimulation (DBS)

Question 157 of 280

□ □

A 46-year-old lady complains of proximal muscle weakness over 6 months. History is otherwise unremarkable. She has no past medical history and is on no medications. She does not drink alcohol. On examination, power is 4/5 proximally in both arms and legs, otherwise unremarkable. Blood investigations are normal except for an elevated creatinine kinase level at 900 U/L. Electromyography demonstrates myopathic features. You order a muscle biopsy to help differentiate which myopathy is present. The results show endomysial lymphocytic infiltrates that invade nonnecrotic muscle fibres. What is the most likely diagnosis?

	Dermatomyositis
	Inclusion body myositis
	Systemic lupus erythromatosis
	Lung cancer
	Polymyositis

Question 158 of 280

□ □

A 32-year-old lady develops a progressive loss of central vision in both eyes over two days. Her eyes are also painful to move. 24 hours later she develops additional paraesthesia in both arms with an associated weakness of both arms. On examination, she has central scotoma of both eyes. She also has a 3/5 global weakness of both arms with hyperreflexia and patchy sensory loss. In the following days, this progresses to paraesthesia and weakness in both lower limbs plus extensor plantar responses. Raised serum levels of which of the following would be most helpful in establishing the suspected underlying diagnosis? helpful in establishing the suspected diagnosis?

	Anti-Hu antibodies
	Antinuclear antibodies
	N-methyl-d-aspartate (NMDA) receptor antibodies
	Anti-Aquaporin-4 antibodies
	Voltage gated potassium channel antibodies

Question 161 of 280

□ □

A 68-year-old man develops a left-sided hemiparesis and facial droop whilst out shopping with his wife at 14:35pm. His initial CT head scan is done at 15:40pm and reveals no intracranial haemorrhage or space occupying lesion. He is given alteplase in the emergency department at 15:50pm.

His post-thrombolysis CT head at 09:00am the following morning reveals a right middle cerebral artery infarction and no evidence of intracranial haemorrhage or haemorrhagic transformation. A 12 lead ECG done in the stroke unit shows atrial fibrillation of 110 beats per minute. He has a persisting dense left-sided weakness several hours post thrombolysis.

Which of the following drugs should be added next?

	Clopidogrel
	Aspirin
	Warfarin
	Unfractionated heparin
	Rivaroxaban

□ Question 162 of 280

A 63-year-old man presents to the emergency department with a 5-minute episode of slurred speech earlier in the day. His wife noticed that his face was drooping to one side as well. He had no arm weakness and is now completely back to normal. He is normally well and on no regular medication and is not allergic to any medication. He works as a plumber and smokes 10 cigarettes per day for the last 40 years and drinks alcohol socially. On further questioning he mentions that he had a similar episode also lasting 5 minutes four days ago whilst at work. On examination, his blood pressure is 135/70 mmHg and his heart rate is 58/min. He has no focal neurology and his cardiovascular and respiratory examinations are unremarkable. He has been given 300mg of Aspirin by the paramedics.

His blood tests are as follows:

Hb	138 g/l
Platelets	$283 \times 10^9/l$
WBC	$8.1 \times 10^9/l$
INR	1.1
PT	13 seconds

Na ⁺	142 mmol/l
K ⁺	4.4 mmol/l
Urea	6.4 mmol/l
Creatinine	89 μ mol/l
CRP	5 mg/l
Total cholesterol	3.8 mmol/l
HDL	1.3 mmol/l

His ECG shows normal sinus rhythm and rate of 65/min.

What is the most appropriate management for this patient?

	Outpatient TIA clinic appointment
	Outpatient CT head and carotid dopplers within the next week
	Admit for urgent (< 24 hours) CT head & carotid dopplers
	Thrombolysis
	Long term clopidogrel

Question 163 of 280

A 57 year-old smoker presents to you with difficulty walking. He used to be able to mobilise unaided but recently he has required the assistance of his wife. He reports being more clumsy than usual. He drinks 3 cans of larger every month. He takes simvastatin for high cholesterol and has been taking aspirin for 10 years since his GP started it. He has lost a lot of weight in recent months, which he can't quantify.

On examination you find that he is cachectic. He has an intention tremor and exhibits dysdiadochokinesia. His gait is broad based. He has bilateral nystagmus on horizontal gaze. On auscultating his chest you find he has a degree of bronchial breathing on the right middle lobe. His observations are unremarkable.

His blood tests are as follows:

Hb	100 g/l
MCV	79.9 fL
Platelets	239 * 10 ⁹ /l
WBC	6.6 * 10 ⁹ /l
Na ⁺	134 mmol/l
K ⁺	4.3 mmol/l
Urea	6 mmol/l
Creatinine	88 µmol/l
anti-Hu antibody	POSITIVE
Bilirubin	6 µmol/l
ALP	62 u/l
Albumin	29 g/l

CT head: No acute intracranial pathology.

What is the most appropriate investigation?

	Chest X-ray
	Vitamin B12 levels
	ECG
	Visual evoked potentials
	Muscle biopsy

Question 164 of 280

You are seeing a 25-year-old woman in neurology outpatients clinic who has been struggling with her migraines for the past 7 years. She has to use abortive medication five to six times a month and she still has issues with her control, with migraines often lasting half a week. Over the seven years she has tried three different triptans, and combinations of NSAIDs (non-steroidal anti-inflammatory drugs), paracetamol and triptans with limited success. Two years ago she had a trial without medication for three months and her headaches got significantly worse. The only other medication that she takes is the combined oral contraceptive pill.

What would be the next step in achieving migraine control?

	Topiramate
	Pizotifen
	Propranolol
	Acupuncture
	Re-attempt withdrawal of medication

Question 166 of 280

An 84-year-old male is reviewed in clinic after a 7-month history of progressive confusion, unsteadiness on his feet and new urinary incontinence. He had previously minimal past medical history and continued to volunteer at his local charity shop, taking ramipril alone for hypertension. On examination, his abbreviated mental test score was 2/10, his gait was wide based and ataxic. A mini-mental state examination scores 17/30. His urine dip demonstrated no positive findings and serum results were unremarkable. Although there has been no history of head trauma, a CT head was performed, demonstrated no acute haemorrhages or infarcts. A subsequent MRI demonstrated large ventricles with periventricular white matter changes. Lumbar puncture demonstrated acellular cerebrospinal fluid with no organism growth. Opening pressure was 16 cm H2O. You arrange a CSF infusion test, demonstrating raised CSF outflow resistance. Which treatment is most appropriate?

	Therapeutic repeat lumbar punctures
	Ventriculoperitoneal shunt
	Donepezil
	Acetazolamide
	Aspirin 300mg

□ Question 168 of 280

A 53 year-old businessman presents to the neurology clinic complaining of weakness and numbness affecting his left hand. One month ago he was irritated when he noticed that the little finger of his left hand was often getting caught when he tried to put his hand in his pocket. Since then he has noticed progressive difficulty using the left hand, associated with an unpleasant tingling sensation.

In the last two weeks he has also noticed difficulty walking, and has tripped over on several occasions. When driving he finds that his right foot often becomes stuck behind the accelerator pedal and he struggles to lift it out.

On examination, in the left hand sensation to pin-prick is diminished over the little finger and medial side of the ring finger, as well as the medial side of the palm. There is weakness of finger abduction and adduction, but thumb abduction is normal. On examination of the legs, you note diminished sensation over the lateral aspect of the right calf, as well as the dorsum of the right foot. When asked to walk on his heels, he finds it difficult to do so, and trips over the right foot.

Investigations are as follows:

Haemoglobin	14.2 g/dl
WCC	$7.1 \times 10^9/l$
Platelets	$420 \times 10^9/l$
ESR	65 mm/hr

Na ⁺	139 mmol/l
K ⁺	4.3 mmol/l
Urea	13.2 mmol/l
Creatinine	171 μ mol/l
Corrected calcium	2.26 mmol/l

ANCA	Positive, with perinuclear staining pattern

PR3 antibodies	Negative
MPO antibodies	Positive

□ Question 168 of 280

A 53 year-old businessman presents to the neurology clinic complaining of weakness and numbness affecting his left hand. One month ago he was irritated when he noticed that the little finger of his left hand was often getting caught when he tried to put his hand in his pocket. Since then he has noticed progressive difficulty using the left hand, associated with an unpleasant tingling sensation.

In the last two weeks he has also noticed difficulty walking, and has tripped over on several occasions. When driving he finds that his right foot often becomes stuck behind the accelerator pedal and he struggles to lift it out.

On examination, in the left hand sensation to pin-prick is diminished over the little finger and medial side of the ring finger, as well as the medial side of the palm. There is weakness of finger abduction and adduction, but thumb abduction is normal. On examination of the legs, you note diminished sensation over the lateral aspect of the right calf, as well as the dorsum of the right foot. When asked to walk on his heels, he finds it difficult to do so, and trips over the right foot.

Investigations are as follows:

Haemoglobin	14.2 g/dl
WCC	$7.1 \times 10^9/l$
Platelets	$420 \times 10^9/l$
ESR	65 mm/hr

Na ⁺	139 mmol/l
K ⁺	4.3 mmol/l
Urea	13.2 mmol/l
Creatinine	171 μ mol/l
Corrected calcium	2.26 mmol/l

ANCA	Positive, with perinuclear staining pattern

PR3 antibodies	Negative
MPO antibodies	Positive

Urine dipstick	+++ blood, +++ protein
Urine microscopy	Red cell casts

Chest radiograph	Clear
------------------	-------

What is the most likely diagnosis?

	Microscopic polyangiitis
	Polyarteritis nodosa
	Wegeners granulomatosis
	Diabetes mellitus
	Entrapment neuropathy

Question 169 of 280

A 23 year-old artist presents after he woke up with headache, neck stiffness, and photophobia. He is normally fit and well, but for the last three weeks has complained of feeling tired and irritable.

On examination, the left side of the palate does not elevate, and the tongue is deviated to the left upon protrusion. The remainder of the neurological examination is unremarkable.

Plain computed tomography of the head is unremarkable.

Lumbar puncture is performed with results of CSF analysis as follows:

Appearance	Turbid
White blood cells	28 cells/mm ³ (95% lymphocytes)
Red blood cells	<1 cells/mm ³
Gram stain	No organisms seen
Protein	1.32 g/L
Glucose	1.4 mmol/L
Serum glucose	7.5 mmol/L

What is the most likely diagnosis?

<input type="checkbox"/>	Meningococcal meningitis
<input type="checkbox"/>	Tuberculous meningitis
<input type="checkbox"/>	Subarachnoid haemorrhage
<input type="checkbox"/>	Skull base tumour
<input type="checkbox"/>	Malignant meningitis

□ □

A 23-year-old male presents with a 5-day history of increasing shortness of breath, exertional dyspnoea and bilateral ankle swelling. He has no previous past medical history and was previous a keen sportsman. On examination, his heart sounds I + II are present with a pansystolic murmur and a displaced apex. Auscultation of his chest demonstrates bibasal crackles. His ECG demonstrates a PR interval of 190 ms but sinus rhythm. Further neurological examination demonstrates bilateral partial ptosis noted associated with bilateral foot drop. You also note slow release of finger flexion. What is the underlying diagnosis?

	Myotonic dystrophy
	Myasthenia gravis
	Inflammatory myositis
	Facioscapulohumeral dystrophy (FSD)
	Guillain Barre syndrome

Question 171 of 280

□ □

A 32 year-old accountant presents to the neurology clinic.

For the last year he has been troubled by severe headaches. These occur in the morning, sometimes waking him from sleep. There is a sudden onset of stabbing pain behind the left eye, at the onset of which he feels the need to pace around the room, pounding his head in an effort to ease the pain. During the attacks his left eye is watery and his nose is congested. On more than one occasion he has noticed that his right pupil appears enlarged during the attacks. He tells you very clearly that the pain is so severe that at times during the attacks he has considered jumping out of the top floor of the office building where he works. Each attack lasts one or two hours, and between the attacks he feels fine.

He shows you a detailed headache diary in which he has documented every attack over the last year. For example, in January he had a period of nine days in which attacks occurred several times daily, but in February and March he was headache free. During April he developed severe headaches which occurred almost every day until June. He then had another period of relief until August, and so on.

He has no other past medical history and no allergies.

Examination is unremarkable.

What is the best treatment for prophylaxis of this man's headaches?

	100% oxygen
	Verapamil
	Sumatriptan
	Propranolol
	Lithium

Overall score: **0%**

□ Question 172 of 280

A 20-year-old man is referred to neurology after presenting at the emergency department. The patient reported suffering a head injury during a rugby match approximately 24 hours ago. He had presented to the hospital due to symptoms of an ongoing headache and an inability to concentrate when he had returned to work that morning.

The patient had hit his head on the knee of another player while attempting to make a tackle. The patient did not lose consciousness after his injury but had been mildly disorientated and so took no further part in the match. The patient had gone home to rest and had experienced a moderate generalised headache that had not responded to paracetamol. Ever since the injury he described feeling 'in a fog' and had had a disrupted night's sleep. At no point after the injury had the patient lost consciousness, suffered a seizure or vomited. The patient also denied any pain or discomfort associated with his neck.

The patient was normally in excellent physical health with no significant previous medical problems. In particular, the patient had no personal or family history of bleeding or clotting disorders. The patient took no regular medications and had no known drug allergies. The patient was a semi-professional rugby player who worked part-time in a coffee shop.

The patient was alert and fully orientated to time, place and person. External examination of the patient's head and neck was unremarkable; in particular, there was no significant bruising to the patient's orbits or behind his ears and there was no evidence of haemotympanum. No evidence of focal neurology was found on detailed examination of the patient's cranial nerves and peripheral nervous system.

What is the appropriate initial management of the patient's head injury?

	Resume normal activities but avoid contact sports for 7 days
	CT brain scan within 8 hours of presentation
	MRI brain scan within 24 hours of presentation
	Complete physical and mental rest for 2-3 days
	Admit to hospital for observation for 48 hours

Overall score: **0%**

Question 173 of 280

A 17 year old Caucasian male with no past medical history presents with his first episode of sudden onset left leg weakness and numbness on his anterior left thigh, of sudden onset and persistent after 4 days. On examination, you note 3/5 weakness on flexion of his left hip and loss of sensation to light touch, pain and temperature on his anterior left thigh in the sensory nerve root L1 distribution. A contrasted MRI scan of the patients spine reveals a hyperintense T2 signal partially within the left side of the cord at the L1, with corresponding enhancement with gadolinium. No masses were observed. Further imaging of the brain is awaited. What is the diagnosis at present?

<input type="checkbox"/>	Multiple sclerosis
<input type="checkbox"/>	Left spinal cord tumour
<input type="checkbox"/>	Left anterior spinal ischaemic stroke
<input type="checkbox"/>	Left transverse myelitis

Question 174 of 280

You are working in a neurology outpatient clinic seeing a patient referred from a local GP clinic. He's a 42-year-old man who has been troubled by severe headaches over the past half a year. These headaches are the worse that he's ever had in his life, describing them as far worse than the compound fracture he sustained three years ago. These headaches tend to happen most nights at around 2am just after he falls asleep. He often paces around his kitchen for a couple of hours and often resorts to bashing his head against the fridge the pain is so bad. When probed further he mentioned that he gets a sense of fullness in his right ear (which is the side that the headache most often occurs on). He remembers having a similar problem a couple of years ago that lasted a few months before resolving on their own.

What medication is most likely to prevent these headaches?

	Oral triptan
	Home oxygen
	Pizotifen
	Propranolol
	Verapamil

□ □

A 25-year-old female presents to clinic complaining of weakness in her upper and lower limbs primarily in the evening, most noticeable when walking up stairs. She is also having trouble keeping her eyes open when driving long distances but denies feeling tired.

On examination, she develops bilateral ptosis when staring upwards for an extended period and her proximal arm strength pathologically fatigues after repeated exertion.

Her nerve conduction tests reveal a decrement in the amplitude of the compound muscle action potential on repetitive nerve stimulation.

Before commencing immune suppression for a patient with the syndrome described above, which of the following medications may provide symptomatic relief?

	Pyridostigmine
	Propranolol
	Donepezil
	Baclofen
	Modafinil

□ Question 176 of 280

A 60-year-old male with a history of hypercholesterolaemia is brought to the emergency department with a 3-hour history of right sided body weakness and an inability to talk. The weakness was gradual in onset and has been progressing thereafter.

The patient has a history of peptic ulcer disease secondary to H.Pylori infection. He was treated with omeprazole, clarithromycin and amoxicillin-clavulanic acid. A recent upper GI endoscopy done 2 months ago was normal.

His medication includes omeprazole 20mg daily, atorvastatin 40mg daily and he takes paracetamol occasionally for joint pains.

On examination, he has a blood pressure of 140/80mmHg. He is aphasic, the tone on the right side is increased with the muscle power being 2/5 in the right upper limb proximally and distally while it is 1/5 in the lower limb both proximally and distally. There is no evidence of meningeal irritation and his pupils are normal.

Lab investigations reveal

Hb	150 g/l
Platelets	450 * 10 ⁹ /l
WBC	13.0 * 10 ⁹ /l

Na ⁺	138 mmol/l
K ⁺	4.4 mmol/l
Urea	6.9 mmol/l
Creatinine	118 µmol/l

ECG: Sinus tachycardia with occasional ventricular ectopics

CT scan brain: no evidence of cerebral haemorrhage, suspected left middle cerebral artery infarction.

What is the most appropriate management option for this patient?

	Aspirin, clopidogrel, IV fluids and bowel and bladder care
	Thrombolysis with alteplase
	Modified release dipyridamole
	Anticoagulation with LMWH
	Anticoagulation with apixaban

Dashboard

Question 177 of 280

□ □

A 64-year-old woman attends neurology clinic after referral from her GP with intermittent episodes of facial pain. She had first noticed symptoms around 10 months previously and recalled her first attack had occurred when taking her grand-children to a fireworks display. Pain episodes were described as a severe 'sawing' pain affecting the right side of her face that lasted one to two minutes before resolving completely. Since the onset the patient reported suffering from at least one attack on most days, with the frequency seeming to increase over time. On direct questioning she reported that on some occasions her nose had become blocked and she had felt sweaty during an episode but that these symptoms were not a major concern in comparison to the severe pain. The patient denied any other symptoms either at the time of the attack and was otherwise in good health with no recent history of weight loss. There was no family history of neurological disease.

A full neurological examination was performed with particular findings of normal pupillary reflexes, visual acuity and colour vision. There was no evidence of facial sensory deficit or facial nerve palsy. A peripheral neurological examination was likewise unremarkable.

Helpfully (although uncomfortably for the patient), a new episode of pain began during the course of the consultation. A further examination was conducted and conjunctival injection and slight eyelid oedema of the right eye were noted. In addition, the patient was noted to be sweating, markedly more profuse on the right side of her face. She also confirmed the onset of a blocked nose sensation at the onset of pain.

What is the most likely diagnosis causing the patients symptoms?

	Trigeminal neuralgia
	Multiple sclerosis
	Horners syndrome
	Short unilateral neuralgiform pain with autonomic symptoms
	Atypical trigeminal neuralgia

Overall score: **0%**

Question 178 of 280

□ □

A 25 year old man presented to the Emergency Department with acute onset, rapidly progressive weakness in all the four limbs following a bout of severe colicky abdominal pain which lasted for 10 days but eventually subsided. The abdominal pain was located around the umbilicus, stabbing in nature, radiated towards the back, and was associated with nausea and intermittent constipation. Patient reports weakness originating in both arms then affecting both the lower limbs. He also complains of difficulty in closing his lips and eyes, and has uncontrolled salivation from the angles of the mouth. He denied any history of paraesthesia, sphincteric disturbances, epileptic fits or dark colored urine during any of the episodes. No definite history of any drug intake prior to both the episodes could be ascertained.

Physical examination revealed bilateral facial palsy of lower motor neuron (LMN) type together with flaccid quadriparesis which was more marked distally with bilateral wrist drop. Deep tendon reflexes were diminished in both upper and lower limbs. There was no sensory loss.

Initial lab values showed WBCs $8.9 \times 10^9/L$, Hemoglobin of 12g/L, Sodium of 132mmol/L, and ESR of 35mm/Hr. His temperature was 36.5 C and pulse 83/min. His blood pressure was 130/83 mm/Hg and oxygen saturations were 98% on air. A lumbar puncture was performed and CSF studies were normal.

Which of the following is most likely to be diagnostic?

	CT scan with contrast of abdomen
	MRI brain with contrast
	Urine screen for Vanillylmandelic acid (VMA)
	Urine screen for Aminolevulinic Acid (ALA) and Porphobilinogen (PBG)
	Measurement of urinary and stool porphyrins

Dashboard

Overall score: 0%

Question 180 of 280

□ □

A 64 year-old man presents to the Emergency Department with his family. His wife is concerned about his behaviour during the past week. He has been intermittently confused, and sleeping during the day. Both of which is abnormal for him.

On examination, he is alert and looks well. He has mild neck stiffness, with no photophobia. The rest of the neurological examination is normal.

A CT scan reveals no abnormality.

An electroencephalography shows generalised slowing.

Hb	130 g/l
Platelets	$232 \times 10^9/l$
WBC	$14 \times 10^9/l$
Serum glucose	9 mmol/L

Which lumbar puncture result would most likely support your diagnosis?

	Opening pressure: 14 cm H ₂ O WCC- 2 cells/ μ L Glucose- 7 Protein- 30 mg/dL
	Opening pressure: 28 cm H ₂ O WCC- 500 cells/ μ L (>90% polymorphonucleocytes) Glucose- 3.5 Protein- 65 mg/dL
	Opening pressure: 18 cm H ₂ O WCC- 5 cells/ μ L Glucose- 8

	Protein- 65 mg/d
	Opening pressure: 22 cm H2O WCC- 100 cells/μL (lymphocytic predominance) Glucose- 8 Protein- 54 mg/d
	Opening pressure: 33 cm H2O WCC- 450 cells/μL Glucose- 2 Protein- 65 mg/d

Question 181 of 280

□ □

A 45 year old male is brought into A&E by his partner. He is known to be HIV +ve and his partner reports good compliance with his medications since his diagnosis 4 years ago. A collateral history reveals persistent confusion over the past 3 weeks. His past medical history includes outpatient treatment 2 years ago for lymphogranuloma venereum and type 2 diabetes mellitus. On examination, the patient is not orientated in time or place. He scores 0/10 on the abbreviated mental test. Both heart sounds are present, include a mild early diastolic murmur. Neurological examination is difficult due to poor patient compliance but you note absent reflexes in both lower limbs, with an upgoing plantar on the left and withdrawn plantar on the right. You also note that he has erythematous soles on both feet. Blood tests and blood glucose are awaited. What is the most likely diagnosis?

	Subacute combined degeneration of the cord
	Motor neurone disease
	Neurosyphilis
	Hypoglycaemia and diabetic peripheral neuropathy
	HIV dementia and peripheral neuropathy

Question 182 of 280

□ □

A 37 year old Japanese female presents with her second episode of loss of colour vision and significant visual acuity impairment in both eyes. Three days later, she complains of vomiting, acute urinary retention, requiring urinary catheter insertion, and inability to move either leg. On examination, she was unable to correctly name any Ishihara plates. A MRI of her brain and spine demonstrates multiple hyperintense T2 white matter lesions in her spine suggestive of demyelination, one of which extends from C5 to T1. Which investigation confirms the diagnosis?

	Lumbar puncture for oligoclonal bands
	Repeat MRI spine with diffusion weighting
	Serum aquaporin 4 antibody
	Serum anti-NMDA antibody
	Repeat MRI spine with gadolinium contrast

Dashboard

Question 183 of 280

The emergency department registrar asks for your advice regarding a 67 year-old female patient who presented with an acutely painful right eye. On examination the right pupil is fixed in mid-dilation and not responsive to light. The conjunctiva is injected. The patient is clearly in considerable pain and has vomited twice in the department. The emergency department physicians have given intravenous analgesia and anti-emetics. You refer urgently to ophthalmology.

What is appropriate initial treatment?

	Topical pilocarpine
	Urgent iridotomy
	IV acetazolamide
	Topical latanoprost
	Topical brimonidine

□ Question 184 of 280

A 32 year old man presented to the Emergency Department with a severe headache. The headache had started suddenly that evening while the patient was at home with his girlfriend watching television. The patient described his headache as an intense throbbing pain felt all across his head. The pain had started very quickly with the patient reporting a severity of 10 / 10 within 30 seconds. The pain had eased slightly following some morphine given by the ambulance crew. The patient denied any symptoms of neck stiffness or photophobia. There were no visual symptoms and no weakness in the patient's limbs or abnormal sensation.

The patient had no previous past medical history and did not normally suffer from headaches. He took no regular medications. The patient worked as a retail assistant and lived with his girlfriend. He rarely drank alcohol but did smoke cannabis on several occasions each month. The patient's girlfriend reported that the patient had smoked cannabis that evening prior to suffering his headache.

On examination, the patient was in visible discomfort due to his headache although had no meningitic signs. Glasgow Coma Score was 15/15 and the patient was afebrile. Cranial and peripheral nerve examination was unremarkable.

Further analgesia was given to the patient and investigations requested as detailed below.

CT brain: no evidence extra-dural or sub-dural bleeding; no intracerebral haemorrhage or sub-arachnoid blood; no evidence of cerebral infarction; normal ventricular system; no radiological contra-indication to lumbar puncture

Cerebrospinal fluid results:

Red cell count	1 / mm ³
White cell count	2 / mm ³
Pprotein	0.75 g / L
Glucose	60 % of serum value
Microscopy	No organisms seen
Red cell breakdown products	Negative
Opening pressure	19 cmCSF

Following initial investigation as above, the patient continued to experience severe recurrent headaches similar to that experienced at presentation and was observed to have a short, generalised seizure on the admission ward prompting further investigation.

CT angiography: diffuse arterial beading identified; results otherwise as for previous CT head

What is the cause for the patient's headache?

	Atypical migraine
	Cervical artery dissection
	Reversible cerebrovascular vasoconstriction syndrome
	Posterior reversible leucoencephalopathy syndrome
	Pituitary apoplexy

Dashboard

□ Question 185 of 280

□ □

A 24-year-old man is referred to the neurology clinic by his GP. He describes a four month history of left-sided numbness and intermittent tingling. This mainly affects his left arm but he occasionally has symptoms in the left leg. There is no history of headaches, visual problems or weakness.

His GP has performed a series of blood tests including a full blood count, urea and electrolytes, vitamin B12 and C reactive protein, all of which were normal.

Neurological examination today was normal other than reduced sensation in the left C6/7 dermatome.

A MRI head is performed. The T2 images are shown below:

Question 186 of 280

□ □

A 35-year-old female presents to the Emergency Department with worsening lower limb weakness over a three day period. She is now unable to walk and feels that her fingers are becoming clumsy. On examination her heart rate is 65 beats per minute and regular, her blood pressure is 125/70 mmHg and her respiratory rate is 20 breaths per minute. She has absent ankle and knee jerks and reduced reflexes in the upper limbs.

Her cerebrospinal fluid (CSF) study shows an elevated protein with a normal white cell count. Given her likely diagnosis, which of the following parameters is most important to measure throughout her admission?

	Lower limb power
	Serial CSF protein levels
	Forced expiratory volume over 1st second (FEV1)
	Postural blood pressure
	Forced vital capacity (FVC)

Dashboard

Overall score: 0%

Question 187 of 280

□ □

A 68 year old female presents via blue light ambulance to the emergency department with a first seizure, witnessed by her husband. He describes a sudden onset limb jerking lasting for around 6 minutes, associated with urinary incontinence and tongue biting, with a period of confusion and drowsiness immediately after. He is not aware of her having had any previous seizures, she has no other past medical history and does not take drugs on a medical history. He however does describe her to be 'not quite herself' over the past four weeks, when she appears to have been extremely agitated and occasionally extremely paranoid. He had thought it to be linked to her not feeling very well, during a period when she had complained of a 'flu-like' headache, generalised muscle ache and a non-productive cough.

You examine her, finding significant gait and limb ataxia with no truncal ataxia. Her blood tests are unremarkable except for positive anti-NMDA antibodies. Her MRI scan demonstrates swelling in bilateral limbic cortices and other no other intracranial abnormalities. She has declined a lumbar puncture and is thought to retain capacity.

Which investigation would most likely provide the underlying diagnosis?

	CT abdomen/pelvis with contrast
	Lumbar puncture
	Nerve conduction studies and EMG
	MRI spine
	Muscle biopsy

Dashboard

Question 188 of 280

□ □

A house officer is asked to review a patient on her ward as the nurses are concerned about the patient's speech. The house officer reports that the patient has unilateral weakness of her right face, arm and leg, dysphasia and a visual field defect. She reports that reflexes are brisk on the right and that the tone of the limbs is increased. There is no disdiadokokinesis on the left, but she is unable to assess on the right arm. The patient's heart rate is 65, blood pressure 198/100 mmHg and respiratory rate 14. Jugular venous pressure is 2cm above the sternal notch. Pupils react to light and are consensual. The patient's family are present who report that the symptoms were sudden in onset. The family are unsure about past medical history, but a list of medications includes warfarin, bendroflumethiazide, ramipril, atorvastatin and allopurinol. A CT head reveals a cerebral infarct.

How would this stroke be classified?

<input type="checkbox"/>	Partial anterior circulation stroke
<input type="checkbox"/>	Total anterior circulation stroke
<input type="checkbox"/>	Posterior circulation stroke
<input type="checkbox"/>	Lacunar syndrome
<input type="checkbox"/>	Thalamic stroke

□ Question 189 of 280

□ □

A 29 year old man presents to the stroke ward following a right sided middle cerebral artery territory infarct. You are reviewing him 4 weeks after as an outpatient. Whilst taking a history from him and his father you find out that he had a normal delivery and early development and initially performed well in school. However from about the age of 12 he started developing complex partial seizures with secondary generalisation that were difficult to control with medications and started to struggle in school.

Since adulthood, he has suffered from frequent migraines that have again been difficult to treat with medications. He also suffers from recurrent vomiting although a thorough gastroenterological assessment including OGD with biopsies could not find any cause for the vomiting.

When aged 26 whilst out walking, he suddenly became very dizzy and unable to walk properly. These symptoms resolved in a day and he never sought medical attention. Since that incident he has been left with a tremor that now makes his work as a painter almost impossible to do. He has also noticed that he is becoming more fatigued by walking. He goes to the gym regularly and is able to lift less and less weights as time has progressed. His mother died suddenly aged 37

Medications included: carbamazepine, clopidogrel and atorvastatin.

Examination

- Height 4ft 11inches (150 cm)
- Generalised muscle weakness with some atrophy
- Left upper limb power 3/5 right upper limb power 5/5
- Right upper limb power 5/5 left upper limb power 5/5
- Lateral nystagmus 5 beats
- Dysdiadochokinesia
- Moderate intention tremor
- MMSE 25/30

□ Question 189 of 280

□ □

A 29 year old man presents to the stroke ward following a right sided middle cerebral artery territory infarct. You are reviewing him 4 weeks after as an outpatient. Whilst taking a history from him and his father you find out that he had a normal delivery and early development and initially performed well in school. However from about the age of 12 he started developing complex partial seizures with secondary generalisation that were difficult to control with medications and started to struggle in school.

Since adulthood, he has suffered from frequent migraines that have again been difficult to treat with medications. He also suffers from recurrent vomiting although a thorough gastroenterological assessment including OGD with biopsies could not find any cause for the vomiting.

When aged 26 whilst out walking, he suddenly became very dizzy and unable to walk properly. These symptoms resolved in a day and he never sought medical attention. Since that incident he has been left with a tremor that now makes his work as a painter almost impossible to do. He has also noticed that he is becoming more fatigued by walking. He goes to the gym regularly and is able to lift less and less weights as time has progressed. His mother died suddenly aged 37

Medications included: carbamazepine, clopidogrel and atorvastatin.

Examination

- Height 4ft 11inches (150 cm)
- Generalised muscle weakness with some atrophy
- Left upper limb power 3/5 right upper limb power 5/5
- Right upper limb power 5/5 left upper limb power 5/5
- Lateral nystagmus 5 beats
- Dysidiadochokinesia
- Moderate intention tremor
- MMSE 25/30

Hb	14.7 g/dl
Platelets	256 * 10 ⁹ /l
WBC	8.6 * 10 ⁹ /l

Na ⁺	140 mmol/l
K ⁺	4.5 mmol/l

Question 190 of 280

□ □

A 23-year-old university student presented with a year long history of occipital headache. This was worse on coughing, sneezing and straining and partially relieved by lying flat. On one occasion the headache had been associated with vomiting. She had previously consulted her family doctor who was treating her for migraine. Over the past two months she had noticed pain in her both arms and felt unsteady on her feet.

On examination touching her arms caused pain and there was reduced appreciation of pinprick and temperature sensation throughout both arms. Tone, power and reflexes in the upper limbs were normal. On testing upper limb co-ordination there was some past-pointing and a very mild intention tremor. On inspection of the feet there was pes cavus and Rombergs test was positive. Again tone, power and reflexes were normal in the lower limbs and plantars were downgoing. Proprioception was impaired with absent joint position sense until the level of the knee. Vibration sensation was impaired in both feet.

Given the clinical findings outlined above which of the following is the most likely diagnosis?

	Syringomyelia
	Friedrichs ataxia
	Brown-Sequard syndrome
	Charcot-Marie-Tooth disease
	Multiple sclerosis

Question 191 of 280

□ □

A 29-year-old man has developed a gradual onset of bilateral leg weakness over the last 24 months such that he now needs to walk with crutches. He is also intermittently incontinent of urine. He will also often fall over in the dark because he feels his balance is worse then. He has never noticed any other symptoms prior to these. He has no significant past medical conditions. He works as an accountant. He went travelling for some years in his early 20's to the Carribean, Japan and Africa. He admits occasional intravenous drug use whilst travelling and getting a tattoo. He also has casual sexual contact with sex workers occasionally whilst travelling and does not recall using barrier contraception. On examination, you find hyperreflexia bilaterally in the legs with upgoing plantar responses. He has loss of vibration and joint position sense in the legs. Legs are 3/5 power in the knee and plantar extensors and 4/5 in the flexors. He has a stomping gait. Routine blood tests plus HIV screening come back unremarkable. MRI brain and whole spine show areas of demyelination in the lumbar spine. Which test would you do to confirm the most likely suspected cause of his symptoms?

	Serm JC virus levels
	Serum and CSF HTLV-1 antibody levels
	Syphilis serology
	Hepatitis B serology
	Paired serum and cerebrospinal fluid (CSF) oligoclonal band levels

□ Question 192 of 280

□ □

An 86-year-old lady was admitted to the acute medical admissions unit having been referred by her GP with acute confusion. Three days ago she was treated by her GP with trimethoprim 200mg BD for a presumed urinary tract infection, her nursing home having complained of new urinary incontinence and offensive smelling urine. Unfortunately, she continued to deteriorate and on the day of admission had become rather confused and unable to mobilise, leading to the admission. Her past medical history comprised Alzheimer's disease, hypertension, hypercholesterolaemia and osteoarthritis for which she was prescribed donepezil 10mg OD, amlodipine 5mg OD, atorvastatin 20mg ON and paracetamol 1g QDS. She was usually able to mobilise independently and suffered from intermittent confusion, though she was able to hold lucid conversations with her care workers. She had a daughter who resided abroad who had not made contact with her in several years and did not have a lasting power of attorney or advanced directive in place.

Examination revealed a very unwell elderly lady. Her temperature was 39.6°C, heart rate 122 bpm, respiratory rate 26/min and blood pressure of 97/58 mmHg. Examination of her cardiovascular system revealed the presence of a bounding peripheral pulse and a capillary refill time of three seconds. Examination of her respiratory system revealed tachypnoea. Examination of her abdomen revealed no abnormalities. She was not compliant with formal neurological examination; her GCS was 14 (E4 S4 M6). She was very confused and unable to maintain a formal conversation; her speech did not resemble any form.

When the doctor proceeded to perform venous cannulation, she became very aggressive and hostile. She refused all forms of treatment, stating that she did not require medical treatment and requested to leave the ward immediately. She did not appear to comprehend the risks of refusing medical admission and was unable to recall the information disseminated.

What is the next best management option?

	Seek opinion from family members
	Apply for formal Deprivation of Liberty Order and proceed with treatment once obtained
	Respect the wishes of the patient and arrange for urgent GP follow up
	Section under 5(2) of the Mental Health Act (MHA) and proceed with treatment
	Proceed with treatment under the Mental Capacity Act (MCA)

Question 194 of 280

□ □

A 46 year old female presents with her third episode of diplopia in two years. During the first episode 3 years ago, her medical notes record that she was unable to abduct her left eye and had a left partial ptosis, which in subsequent clinic follow-up was found to have been resolved after 4 weeks. Her second episode occurred 6 months ago, during which she experienced mild vertical diplopia, diagnosed by GP as a fourth nerve palsy secondary to diabetic microvascular disease, which improved to normal after 6 weeks.

Her past medical history includes insulin dependent diabetes, with moderate control HbA1c (IFCC 39 mmol/mol), autoimmune hypothyroidism and vitiligo. She is a non-smoker. On examination today, you note a failure of vertical upgaze in her right eye and 50% failure of adduction with a 50% partial ptosis. Both pupils were equal and reactive.

Her admission blood tests were unremarkable. A MRI head and orbits demonstrated no orbital or intracranial pathology. Which of the following history is most likely to produce the underlying diagnosis?

	Single fibre EMG
	Lumbar puncture including oligoclonal bands
	Neurogenetics
	CT chest/abdomen/pelvis
	ANA, ANCA, complement autoimmune screen

□ Question 195 of 280

A 52-year-old man is admitted to the stroke unit with a right total anterior circulation syndrome (TACS) infarct. He arrived at hospital 2.5 hours after the onset of his symptoms and was treated with intravenous alteplase at 3 hours post-onset.

He is known have an atrial septal defect which was discovered after a murmur was heard at a routine insurance medical several years ago. He works in the oil business and has recently returned from a business trip to Saudi Arabia.

On examination the following day there subtle signs of improvement with increased movement in his left hand. However, the rest of his arm remains flaccid and he has persisting dense hemiplegia affecting his right leg. He has a notable homonymous hemianopia on examination. A routine CT Brain 24-hours post-thrombolysis revealed established ischaemic changes in the MCA territory with new petechial haemorrhage along the border of the infarct.

Later that evening, his conscious level falls. His Glasgow Coma Scale changes from E4 M6 V2, to E2, M4 V2. His blood pressure is 187/112 mmHg.

Urgent bloods reveal:

Haemoglobin	120 g/l
Prothrombin time	27 seconds
Activated partial thromboplastin time (APTT)	49 seconds

What intervention is likely to have the most benefit?

	Correction of coagulopathy
	Decompressive craniotomy
	Control of blood pressure
	Protamine sulphate
	Tranexamic acid

Question 196 of 280

□ □

You are asked for advice from a GP regarding a 52 year old woman with a diagnosis of Generalised Anxiety Disorder. She is having symptoms of free floating anxiety for the past 5 years and this is causing work and relationship difficulties. The GP tells you that 5 years ago he was admitted to hospital with epigastric pain and anaemia and required a therapeutic endoscopy. A repeat endoscopy showed a small ulcer at D2 with a small amount of ooze which was treated with adrenaline. She still suffers from occasional heartburn.

She also has a history of alcohol dependency. She drank 20 units of alcohol per day for 20 years but has now cut down to 1-2 units per day. An ultrasound scan of the abdomen showed mild portal hypertension, hepatomegaly and no gastric varices. There is no history of deliberate self harm or overdoses. She takes Vitamin B Co strong and thiamine 100mg PO OD and omeprazole 20mg PO OD and is compliant with medication currently but has a history of non compliance with medication.

Which would be the safest therapy for treatment of his generalised anxiety disorder?

	Clonazepam
	Diazepam
	Sertraline
	Citalopram
	Imipramine

□ Question 197 of 280

A 25 year old Caucasian male presents with his first ever episode of witnessed generalised seizure, with witnessed jerking of his right arm and leg, lasting for 4 minutes terminated by benzodiazepines administered by paramedics. There is no other past medical history and documentation of head injuries. His past medical history includes recurrent epistaxes since childhood and current treatment for a left calf deep vein thrombosis, provoked following two recent long-haul flights from Australia. A thrombophilia screen has subsequently been negative. Family history is unavailable.

On examination, the patient is confused post-ictally and is uncooperative with examination. You note that his pupils are equal and reactive, he is moving all 4 limbs with no obvious focal neurology. There appears to be no visual or sensory neglect. A urinary toxscreen is negative.

His blood tests and arterial blood gas are as follows:

Hb	17.5 g/dl
MCV	87 fl
Platelets	$223 \times 10^9/l$
WBC	$9.2 \times 10^9/l$
Urea	6.6 mmol/l
Creatinine	64 $\mu\text{mol/l}$
CRP	24 mg/l

pH	7.32
PaO ₂	9.1 kPa
PaCO ₂	4.2 kPa
Lactate	4.2 mmol/l
Bicarbonate	16 mmol/l

With sedation, the patient undergoes a CT head, which demonstrates an arterio-venous fistula in his right parietal lobe.

The patient remains an inpatient while discussed for management with neurosurgeons and returns to baseline with no focal neurological deficits. At 48 hours after admission, he develops sudden onset left face, arm and leg weakness and loss of sensation, with flaccid tone, downgoing plantars. A repeat CT head confirms a right middle cerebral artery ischaemic stroke.

What is the unifying diagnosis?

	Malignancy of unclear primary
	Haemorrhagic hereditary telangectasia
	Saddle pulmonary embolus
	Polycythaemia rubra vera
	Paroxysmal nocturnal haemoglobinuria

Dashboard

Overall score: 0%

Question 198 of 280

□ □

A 42-year-old female presented with a 6-month history of weakness affecting her upper limbs. She found that this was worse at the end of the day, particularly if she had been doing a lot of lifting. She also reported occasional difficulty in swallowing at the end of the day, with drinks causing her to cough. She had been prescribed pyridostigmine, but she stopped taking this as she had not noticed any benefit.

On examination, there was a mild partial ptosis, and a slight facial droop bilaterally. Extra-ocular movements were normal. Power in shoulder abduction was grade 4/5 bilaterally, but was reduced to 3/5 after repeatedly abducting and adducting the shoulder 20 times. Tone and sensation were normal.

Initial investigation results are shown below:

Nerve conduction studies: Decremental response to repetitive nerve stimulation

Single-fibre electromyography: Increased jitter

Anti-Jo antibodies: Negative

Anti-Mi2 antibodies: Negative

Anti-acetylcholine receptor antibodies: Negative

Which of the following immunological tests is most likely to contribute to the diagnosis?

	Anti-muscle-specific tyrosine kinase(MuSK) antibodies
	Anti-N-methyl D-aspartate (NMDA) receptor antibodies
	Anti-glutamic acid decarboxylase (GAD) antibodies
	Anti-acetylcholine receptor antibody
	Anti-Hu antibodies

Question 199 of 280

□ □

A 19-year-old university student is reviewed in the general medical clinic with bilateral ptosis. It has developed gradually over the last few months and has now progressed to the extent that he has to tilt his head upwards during lectures. He denies diurnal variation in his symptoms.

His past medical history is unremarkable and he takes no regular medications. He tells you that his mother had a pacemaker fitted due to frequent 'blackouts'.

On examination, you note the presence of bilateral ptosis. He also has impaired abduction and adduction of both eyes. Direct fundoscopy shows black spicules in the periphery of both eyes. An ECG is taken and shows sinus rhythm with first-degree heart block.

Given the likely diagnosis, which additional symptom is he most likely to describe?

	Night blindness
	Syncope
	Tremor
	Flank pain
	Diplopia

Dashboard

□ Question 200 of 280

□ □

A 24-year-old woman is referred urgently to neurology for lower limb weakness. This has been getting gradually worse over the past 4 weeks and she is now experiencing problems walking.

She also complains of bilateral tinnitus which has been present for the past 3 months. This is associated with episodes of vertigo.

On examination both lower limbs have reduced power (3/5), with increased tone and hyperreflexia. The patient has one 1cm tan lesion on his torso but no other skin lesions are noted.

A MRI of his spine is requested:

Question 201 of 280

□ □

A 55-year-old obese man with a history of hypertension, diabetes and angina develops central crushing chest pain whilst gardening alone. He is short of breath and clammy. He takes two puffs of his glyceryl trinitrate spray but has only mild relief from this.

He calls an ambulance but before the ambulance arrives he suffers a cardiac arrest. The ambulance crew arrive and commence cardiopulmonary resuscitation (CPR). Heart monitoring shows him to be in ventricular tachycardia and after a DC shock and a further round of CPR, he recovers cardiac output. He is taken to the local hospital intensive care unit where he remains unconscious. The doctors explain to his family that because of the time between his cardiac arrest and CPR commencing, his brain function may not recover well.

What in patients in coma after a cardiac arrest, what is the most reliable indicator of poor prognosis at 72 hours post arrest?

	Electroencephalogram
	Glasgow coma scale motor score
	Pupillary reflex
	Somatosensory evoked potential
	Gag reflex

□ Question 202 of 280

A 69-year-old retired accountant was seen in the neurology clinic having been referred by his GP. He presented with a three-month history of malaise and weakness. The weakness initially affected his legs, and at times he felt that his legs would not support him standing up. Over the course of the last month, however, he also noticed weakness in his hands, especially his left hand. This was particularly noticeable when he rode his motorbike when he felt that his fingers were not strong enough to apply the brakes. In addition, his wife remarked that his speech had changed in tone though he did not have any difficulties with understanding or expressing speech. His past medical history comprised hypertension, hypercholesterolaemia, depression and hypothyroidism. His medication regimen included amlodipine 5mg OD, atorvastatin 20mg ON, citalopram 20mg OD and levothyroxine 125mcg OD. He also remarked that he had been referred by his GP to the fast track gastroscopy clinic and was pending an appointment for new onset difficulty in swallowing food over the last month. He did not smoke and did not consume alcohol. Upon a systems review, he denied the presence of other symptoms though he did admit to losing 3kg of weight since the onset of his symptoms.

On examination, he appeared cachectic with obvious dysarthria. His blood pressure was 128/78 mmHg and his heart rate was 78bpm. Examination of his cranial nerves revealed the presence of tongue fasciculations with tremulous lips and an absent jaw jerk reflex but was otherwise unremarkable. Examination of his peripheral nervous system revealed small muscle intrinsic wasting of both hands, as well as wasting of his thigh muscles. The tone was reduced in his lower limbs but increased in his upper limbs. He had obvious weakness of all muscle groups, with a grade 4/5 weakness in his lower limbs and proximal upper limb and a grade 3/5 weakness in his distal upper limbs. Fasciculations were present in his thighs and forearms. Both upper and lower limb reflexes were brisk with downgoing plantars. Examination of sensation was normal. Examination of the cardiovascular, respiratory and gastrointestinal systems was unremarkable.

Investigations conducted by the GP prior to referral are as follows:

Hb	111 g/l
Platelets	99 * 10 ⁹ /l
WBC	12.2 * 10 ⁹ /l
ESR	18 mm/hr
CRP	6 mg/l
ANA	positive
Rheumatoid factor	negative

Which one of the following interventions is most likely to be of benefit?

	Mitoxantrone
	Riluzole
	Rivastigmine
	Methotrexate
	Azathioprine

Question 203 of 280

□ □

A 25-year-old female was seen in the neurology clinic with a six-year history of headaches. The headaches occur on average two to three times per week, and she described them as a one-sided pulsating headache with associated nausea and intolerance of light lasting for four-six hours before subsiding. The headaches worsened with exertion and when they occurred she would be disabled from continuing with normal daily activities, instead resorting to taking refuge in a darkened room. She denied the presence of any transient neurological deficit or facial lacrimation, and other than the associated photophobia she denied any ocular involvement. She denied the presence of weight loss or early morning headache. Her past medical history included hypothyroidism for which she was prescribed levothyroxine 125mcg OD.

Investigations conducted are as follows:

TSH	0.36 u/l
-----	----------

MRI: presence of normal intracranial appearances, no evidence of space occupying lesion, intracerebral haemorrhage or mass effect

She was trialled on propranolol 80mg M/R which reduced the frequency of the headaches, but unfortunately she did not tolerate the adverse effects. Which one of the following interventions is most appropriate to prevent the headaches from occurring?

	Amitriptyline
	Gabapentin
	Sodium valproate
	Increase dose of levothyroxine
	Topiramate

□ □

A 36-year-old lady on natalizumab for relapsing-remitting multiple sclerosis develops left leg weakness. Over 3 weeks this progresses to left hemiparesis and visual impairment. She also notices poor memory and struggles to process numbers at work as an accountant. Examination reveals left-sided 4/5 power, right homonymous hemianopia, and an abbreviated mini-mental state score of 21/30. Routine blood tests are unremarkable. MRI brain shows new multiple confluent lesions in the parietooccipital and right motor white matter areas as well as the left occipital area, with no mass effect or enhancement. Which of the following tests is likely to be most helpful in establishing a diagnosis?

	Serum glucose
	HIV serology
	JC Virus serology
	Cerebral angiogram
	Full blood count (FBC)

A 24 year old female known epileptic presents via blue-light ambulance with a generalised tonic-clonic seizures in the Emergency Department. She is currently 24 weeks pregnant and her husband reports she has suffered from epilepsy since she was 5 years old. He extremely distress and is unclear which anti-epileptics she normally takes. On our arrival, the Emergency Department registrar has already administered two intravenous boluses of lorazepam 4mg. At 10 minutes since onset of limb jerking, she continues to jerk all four limbs with low amplitude, rhythmic movements with loss of urinary continence. What is the most appropriate course of action?

	Intravenous phenytoin loading
	Intravenous sodium valproate
	3rd dose of intravenous lorazepam
	Intravenous levetiracetam
	Observe and monitor

Question 210 of 280

□ □

A 67 year old male presents to your neurology clinic with his wife, reporting a 3 month history of worsening vision in his left eye. He is very reluctant to seek any medical help but says that a number of factors have finally convinced him to attend.

Over the past 2 months, he reports a constant and worsening headache, worse at night and with coughing. He has occasionally felt extremely nauseated and vomited on a number of occasions, at least twice waking him from sleep. His wife also notes significant personality change: her husband is a retired farmer who prides him on being a stoic man. She notes that he has become increasingly emotional and occasionally aggressive, which she puts down however to struggling with his symptoms. Prior to these symptoms starting 3 months ago, he has always been fit and well with no past medical or drug history.

On examination, you note a left relative afferent papillary defect with equally sized pupils. Visual acuity in the left eye is 6/60 and 6/9 on the right. Testing of colour vision with Ishihara plates demonstrate 0/17 on the left and 17/17 on the right. A central scotoma is found in the left eye. Fundoscopy of the left eye reveals a pale optic disc with poor vasculature while the right appears swollen. A full range of painless eye movements is demonstrated. The remaining examination of the cranial nerves, upper and lower limbs are unremarkable. Bloods are unremarkable, a MRI head is awaited.

What is the most likely diagnosis?

	Foster-Kennedy syndrome
	Idiopathic intracranial hypertension (IIH)
	Multiple sclerosis (MS)
	Fronto-temporal dementia
	Age related macular degeneration (ARMD)

Overall score: **0%**

□ Question 213 of 280

□ □

You are called to see a 67 year old lady by the Psychiatry SHO who is asking for your opinion on management. Over the past 3 weeks, her husband has become increasingly concerned by her behaviour. She has become suspicious of him and accused him of stealing my true husband Initially the lady would avoid her husband and refuse to eat food that she had prepared but today she threatened him with a knife and the police had to be called.

The psychiatry SHO is concerned as he notes that she was admitted to hospital 5 weeks ago and was treated for a suspected urinary tract infection with intravenous antibiotics. Subsequent testing showed the pathogen to be an extended spectrum beta lactamase producing bacteria. She currently has a temperature of 38.7 degrees heart rate 105bpm regular RR 18 Sats 99% on room air. Her husband notes that she has been spending more time in the toilet over the past 3 weeks but is unsure if this is due to her paranoia. Blood tests have not been acquired at this point due to no co-operation of the patient.

Her husband describes an episode 30 years ago where she required antidepressants, antipsychotics and ECT after a close family bereavement. She also takes amlodipine 5mg PO OD for hypertension. She is otherwise well and has no history of cognitive problems. Her husband states that there is a strong history of mental health problems in her family but he is unable to be more specific.

When you speak to her she appears to be confused and scores 19/30 on the Mini Mental State Examination. She can point to, name and recognise her husband and can also pick him out from pictures. However, she tells you that the man standing next to her is not her husband but a lookalike who has replaced him. Despite all your best efforts to show evidence to the contrary she cannot be persuaded to change her opinion.

Which of the following below would best describe her presentation:

	Delirium causing Cotard syndrome
	Delirium causing Fregoli syndrome
	Delirium causing Capgras syndrome
	Late onset schizophrenia causing Capgras syndrome
	Atypical severe depression

Question 213 of 280

You are called to see a 67 year old lady by the Psychiatry SHO who is asking for your opinion on management. Over the past 3 weeks, her husband has become increasingly concerned by her behaviour. She has become suspicious of him and accused him of stealing my true husband Initially the lady would avoid her husband and refuse to eat food that she had prepared but today she threatened him with a knife and the police had to be called.

The psychiatry SHO is concerned as he notes that she was admitted to hospital 5 weeks ago and was treated for a suspected urinary tract infection with intravenous antibiotics. Subsequent testing showed the pathogen to be an extended spectrum beta lactamase producing bacteria. She currently has a temperature of 38.7 degrees heart rate 105bpm regular RR 18 Sats 99% on room air. Question 214 of 280

□ □

A 28-year-old male presents with feet, hand and perioral paresthesia associated with progressive weakness in his lower limbs over approximately two weeks. On examination he has normal tone and reduced reflexes in his lower limbs, reduced proprioception in feet and hands, and proximal weakness in his lower limbs. His MRI spine was unremarkable.

Other results:

CSF protein	2.0g/L
HIV	negative
Lyme serology	negative
Epstein-Barr virus	negative

What is the correct treatment?

	Intravenous immunoglobulins
	Intravenous methylprednisolone
	Cyclophosphamide infusion
	Pyridostigmine
	Doxycycline

Question 215 of 280

A 28-year-old gentleman student from Germany presents to you with right foot drop ongoing for two weeks with some numbness and tingling of the foot. These symptoms developed after he knelt down to pick something up from the floor. Three years ago he woke up from sleep with clawing of his fourth and fifth digit after having been asleep in a prone position and this lasted a week. Eight years ago he also had a left wrist and finger drop lasting three weeks after he sat on the couch with his left arm draped over the back of the couch for ten minutes. He denies falling asleep or remaining on the couch for a prolonged period. He has no other past medical history of note and has never sought medical advice for his problems. On examination, there is right foot drop (2/5 power) and similar weakness of dorsiflexion and eversion of the right foot. There is also sensory loss over the lower lateral part of the right leg and dorsum of the right foot in all modalities. Reflexes are intact. Neurological examination and general examination are otherwise unremarkable. Which of the following tests would confirm the suspected diagnosis?

	Nerve conduction studies
	Electromyography
	Nerve biopsy
	PMP22 gene testing
	HBA1C

Question 216 of 280

□ □

A 48-year-old lady develops a sudden-onset left-sided headache in the face and neck areas 36 hours ago whilst at rest. It is of 10/10 severity and reached this maximum intensity within seconds. It has not subsided since and is throbbing in nature. She also developed a transient period of loss of vision in the left eye lasting 2 hours before resolving. She also says that 'food tastes funny' since these problems developed. On examination, she has small, sluggishly light-responsive left pupil compared to the right and partial left ptosis. The face is otherwise unremarkable to examine as is the remaining neurological examination. Routine blood investigations are unremarkable. Plain computerised tomography (CT) of the head is unremarkable. Lumbar puncture is negative for xanthochromia. CT angiogram of the head and neck vessels demonstrates a pseudo-lumen of the carotid artery. Which of the following treatments would you initiate?

	High flow 100% oxygen
	Prednisolone
	Indomethacin
	Aspirin
	Acetazolamide

□ Question 218 of 280

A 60 yr old woman went swimming with her family, and after finishing her swim and having a shower, her daughter noted that she became confused suddenly, repetitively asking if they had gone for a swim today. She could not remember events that occurred in the past 24 hours, and when told the answers to her questions, would ask the same question 5 minutes later. There was no change in her personality, no change in her speech, nor any muscle weakness. She is able to recall her address, the names of her daughters and husband, and her date of birth. Her daughter said her mother did not suffer any trauma during the swim, and did not lose consciousness anytime throughout the day. The patient's past medical history includes hypertension and depression, and she takes ramipril 2.5mg once daily, and citalopram 20mg once daily.

On examination the patient was alert, but constantly asked where she was and why was she in hospital. She was afebrile, heart rate 80 bpm, blood pressure 138/68 mmHg, respiratory rate of 18 breaths per minute, and oxygen saturation of 99% on air. Neurological examination was unremarkable, but her abbreviated mental test score was 6/10.

Her investigation results were as follow:

C Reactive protein	4 mg/l
Haemoglobin	14.8 g/dl
White cell count	$5.6 \times 10^9/L$
Na+	142 mmol/l
K+	4.3 mmol/l
Urea	4.2 mmol/l
Creatinine	68 μ mol/l
Corrected calcium	2.32 mmol/l
Plasma glucose	5.8 mmol/l

Computer Tomography (CT) head scan No acute intracranial pathology.

Over the next 12 hours, her memory improves and she is discharged from the observation ward.

What is the best advice for the patient with regards to driving in the future?

	She can drive 4 weeks after the event if the cause has been identified and treated
	DVLA need not be notified, no driving restrictions
	She must be symptom free for 1 year before being eligible to drive
	DVLA must be informed, and her licence will be revoked for 6 months
	She must cease driving until there is satisfactory control of her symptoms

Question 219 of 280

□ □

A 49-year-old male presents to the Emergency Department with sudden onset left sided weakness nine hours ago. His partner has brought him into hospital late after finding him collapsed but conscious in his kitchen after she returned home. His past medical history includes diabetes and hypertension, for which he has been non-compliant with his medications for the past 2 years. On examination, he is drowsy but rousable to minor stimulation. He displays a gaze preference to the right and a left forehead-sparing facial palsy. Power in his left upper and lower limbs score 0/5, right arm and leg score 5/5. He is unaware of his left upper and lower limb being stimulated by painful stimuli. His speech is mildly dysarthric, obeys commands and displays no dysphasic symptoms. His NIHSS score is 18. A hyperacute CT head demonstrates an evolving right middle cerebral artery infarct involving 55% of the right MCA territory. What is the optimal next management action?

	Aspirin 300mg only
	Aspirin 300mg and clopidogrel 300mg
	Aspirin and decompressive craniectomy
	Intravenous thrombolysis
	Intravenous thrombolysis and thrombectomy

Question 222 of 280

□ □

A 60-year-old female presents to the Emergency Department with altered sensation in both hands and reduced visual acuity in the left eye. She states that these symptoms have slowly worsened over a week. She has no issues with bladder or bowel activity.

On examination, she is haemodynamically stable. Of note, she has a sensory loss throughout her arms and legs, but no clear sensory level. Additionally, she has brisk reflexes in both the upper and lower limbs. She also has a visual acuity of 6/36 in the left eye, but normal vision in the right eye, with normal visual fields.

Her MRI scan reveals multiple continuous segments of inflamed spinal cord throughout the cervical region and left optic nerve inflammation. There are no cerebral lesions. Her cerebrospinal fluid (CSF) studies are negative for oligoclonal bands.

Which of the following tests will confirm the diagnosis?

	dsDNA antibodies
	Aquaporin-4 antibodies
	ACh receptor antibodies
	NMDA receptor antibodies
	Neuronal antibodies

Question 223 of 280

□ □

A 43-year-old man is apprehended by the police after a violent assault outside a pub. He is brought to the attention of the duty psychiatrist because he is extremely confused and agitated. He repeatedly says that his wife is having an affair with the Prime Minister. He believes this to be true because of a message encoded in the traffic lights. He also mentions that he has not slept in the last two days.

The psychiatric assessment is interrupted when he has a tonic-clonic seizure, which self-terminates in 3 minutes. He is taken to the local Accident and Emergency department and reviewed by the medical team.

The medical SHO manages to contact his wife, who reports that he is normally fit and well and she last saw him when he left for work five days ago. At that time he appeared normal but complained of a headache, and took some ibuprofen.

During the clerking, he is noted to have repetitive chewing movements of the mouth. Again, the assessment is interrupted by a tonic-clonic seizure which does not terminate after 10mg of intravenous diazepam. After 15 minutes he is loaded with phenytoin. He continues to fit so is intubated and transferred to the Intensive Care Unit. Termination of seizure activity is only achieved after induction of general anaesthesia with thiopentone.

What is the most likely diagnosis?

	Schizophrenia
	Fronto-temporal dementia
	Acute intermittent porphyria
	Post-ictal psychosis
	Autoimmune limbic encephalitis

Overall score: **0%**

Question 226 of 280

A 77-year-old female was brought into hospital after waking with left arm weakness predominantly affecting the hand with a left sided facial droop in an upper motor neuron pattern. Her blood pressure on admission was 175/90 mmHg and her heart rate was 80 beats per minute and in sinus rhythm. Her blood glucose level on admission was 7.2 mmol/L.

Her initial CT brain showed some mild bi-temporal atrophic change and some chronic small vessel ischaemia without any acute ischaemic changes and in particular, no haemorrhage.

She was admitted with a suspected diagnosis of minor ischaemic stroke. Which of the following imaging modalities will confirm the diagnosis?

	CT cerebral angiogram (CTA)
	Fluid attenuated inversion recovery (FLAIR) MRI
	Thin slice non-contrast enhanced CT brain scan
	Diffusion weighted imaging (DWI) MRI
	Formal cerebral digital subtraction angiogram (DSA)

□ Question 227 of 280

A 37-year-old female presents to the medical outpatient department with a progressive loss of libido. She attributes this to persistent diarrhoea, which she has noted over the last 6 months. She has also lost 16kg of weight and feels fatigued. She has noticed that her eyes have become grossly protuberant and she has double vision on looking towards either the right or left. She also experiences painful watering of her eyes.

On examination she has a marked tremor in both hands, her heart rate is irregularly irregular and she has marked exophthalmos. There is an audible bruit on auscultation of the thyroid gland.

Her laboratory investigations reveal:

Hb	130 g/l
MCV	77 fl
MCH	29 pg
WBC	$7.4 \times 10^9/l$
Plt	$430 \times 10^9/l$
TSH	0.03 mU/l (0.4 3.6 mU/l)
Total T4	302 nmol/l (68 174 nmol/l)

CT scan of the orbits reveals taut optic nerves and retro-orbital oedema.

Which of the following would be the most appropriate management of his eye condition?

	Treatment with a block and replace regimen
	Treatment with radioactive iodine
	Treatment with IV methylprednisolone
	Surgical removal of the thyroid gland

	Orbital decompression surgery

Question 228 of 280

□ □

A 32-year-old female presents with four episodes of loss of consciousness within the past 4 weeks. She denies palpitations or chest pain but reports sudden onset binocular black dots in visual fields, occasional flashing lights, dysarthria and hearing loss, all of which resolves after about 60 minutes. She is unsure about the relevance of an occipital headache, onset with frequency of about three times per week for the past year. She denies any limb weakness, altered sensation or facial droop. She has no past medical history or family history of epilepsy. Your neurological examination, including fundoscopy is unremarkable. An EEG is unremarkable. What is the likely diagnosis?

	Cluster headache
	Transient ischaemic attacks
	Basilar migraine
	Bilateral retinal detachment
	Guillain-Barre syndrome

Question 229 of 280

□ □

A 55-year-old cachectic male is brought into hospital after having been found on the floor by his sister, who visits him once a week. She reports a long history of depression and his appetite to have been poor for a number of years. He denies any loss of consciousness episodes, palpitations, chest pain, dysphagia or presyncopal symptoms. When asked how he ended up on the floor, he vaguely reports to have slowly fallen from being generally weak and denies head injury. He does report a recent sore throat and dry cough. He is alert and orientated. On examination, he scores 3 and 4 out of 5 power in all movements. Lower limb reflexes could not be elicited with a tendon hammer but bilateral upgoing plantars are noted. Which treatment might reverse the underlying condition most rapidly?

	IV methylprednisolone
	IV immunoglobulin infusion
	Plasmapheresis
	IV thrombolysis
	IM vitamin B12 + IV pabrinex

Question 231 of 280

□ □

A 25-year-old woman presented with a fronto-temporal headache, mild meningism and low-grade temperature. A CT head is normal and does not show any evidence of increased intra-cranial pressure. You consent the patient for an lumbar puncture, stating that a post-procedure headache is one of the most common procedures. What is the most important preventative measure for a post-procedure headache?

	Re-insertion of the stylet prior to removing the needle
	Ensure adequate hydration
	Male patient gender
	Patient position during the lumbar puncture
	Bed-rest - lying supine post-procedure

Question 232 of 280

A 32-year-old male presents to clinic with shooting pain down both legs for one week and a mildly weak right hand. He does not recall ever having any other remarkable neurological symptoms and has not been diagnosed with any chronic medical illnesses.

He is right handed, and on examination, he has reduced fine motor control in the right hand with a brisk brachioradialis reflex on the right side. He also has subjective sensory disturbance over his trunk, but no objective sensory loss.

You suspect multiple sclerosis (MS), which findings are required to make the diagnosis of relapsing remitting MS?

	A gadolinium enhancing lesion on MRI in a typical region for MS
	At least 2 separate MRI lesions typical of MS that are of different ages (i.e 1 enhancing and 1 not)
	Oligoclonal bands in CSF
	Optic neuritis on examination and abnormal visual evoked potentials
	Observe the patient and await a second clinical episode before a diagnosis can be made

Dashboard

Question 233 of 280

□ □

A 27 year old lady with relapsing-remitting multiple sclerosis (MS) is referred to your clinic. She was diagnosed at age 18 and has been managed on interferon β 1a, with only four relapses in her total history. She has made good recovery from all four relapses and the only finding on neurological examination is of mild dysdiadochokinesis of the left arm. She scores functionally very well on an expanded disability status scale (EDSS) and has no disability as a result.

She is planning her first pregnancy and wanted advice on how her MS may be affected. She has already been advised on stopping interferon β 1a in preparation for pregnancy. Aside from the impact of stopping interferon β 1a, she wants to know how pregnancy itself will affect her MS. Which of the following is most accurate?

	Relapse rates may decrease during pregnancy, increase at 3-6 months post-partum then return to pre-pregnancy rates.
	There is an increased risk of developing visual disorders associated with MS.
	There is a 30% chance that her RRMS will evolve into progressive MS.
	There is a 15% chance that her relapse rate will decrease for the five years following pregnancy.
	Relapse rates may increase during pregnancy, then return to pre-pregnancy rates at 9 months post-partum.

Question 234 of 280

A 50-year-old man is seen in the Emergency Department with fevers. He has been feeling generally unwell for the last 3 days and has just returned from a 2 week stay with his sister who lives on the other side of the U.K. He has had a mild non-productive cough and shortness of breath. He has had no vomiting, diarrhoea, dysuria or abdominal pain.

He has a past medical history of epilepsy, schizophrenia, hypertension and diet-controlled type 2 diabetes.

On examination he has a temperature of 38.3 °C and is saturating at 94% on room air. His heart rate is 111 beats per minute and blood pressure is 118/75 mmHg. He looks clammy and pale but systems examination is otherwise unremarkable.

His chest x-ray shows clear lung fields.

His blood tests are as follows:

Hb	140 g/l	Na ⁺	141 mmol/l
Platelets	443 * 10 ⁹ /l	K ⁺	3.7 mmol/l
WBC	1.5 * 10 ⁹ /l	Urea	7 mmol/l
Neuts	0.6 * 10 ⁹ /l	Creatinine	98 µmol/l
Lymphs	0.5 * 10 ⁹ /l	CRP	170 mg/l

He is started on broad spectrum antibiotics and fluids.

Which drug is most likely to have precipitated this condition?

	Clobazam
	Clozapine
	Phenytoin

	Sodium valproate
	Venlafaxine

Question 235 of 280

□ □

A 78 year old male presents to you with progressive weakness in his arms. He first saw his GP about 4 months ago complaining of a weakness in his right wrist and was told he had carpal tunnel syndrome, for which he was placed on a waiting list to see the orthopaedic surgeons. Over the next 4 months, he noticed progressive weakness in his right wrist and in bending his right elbow. He noted his right hand was becoming increasingly wasted. Two months ago, he noted similar weakness in his left wrist. He reports no changes to sensation, normal speech and swallowing. On examination, cranial nerves were unremarkable.

Both hands were markedly wasted with significant loss of musculature and fasciculations bilaterally. Reflexes were muted in both upper limbs with negative Hoffman's sign. Sensory examination in the upper limbs were unremarkable, he was unable to perform finger-nose examination. Examination of the lower limbs was also unremarkable but the patient felt a subjective weakness in both hip flexion. MRI imaging of the patients head and spine demonstrated no significant lesions. Nerve conduction studies demonstrated f waves and H reflexes, multiple focal areas of demyelination and motor neuropathic blocks.

What is the optimum management?

	Intravenous cyclophosphamide
	Intravenous immunoglobulin
	Intravenous methylprednisolone
	Plasma exchange
	Riluzole

Dashboard

Question 237 of 280

A 27-year-old woman is admitted to the Emergency Department following a road traffic accident. Primary survey reveals a right-sided haemothorax but she is haemodynamically stable. She is only responding to voice. A CT scan of her head (with contrast) is performed:

© Image used on license from [Radiopaedia](#) 

What does the scan show?

- Subdural haematoma
- Subarachnoid haemorrhage
- Extradural haematoma
- Brain contusion
- Meningioma

The CT scan shows a extra-axial biconvex collection associated with fracture suggestive of extradural haematoma.

[Next question](#)

Head injury: types of traumatic brain injury

Basics

- primary brain injury may be focal (contusion/haematoma) or diffuse (diffuse axonal injury)
- diffuse axonal injury occurs as a result of mechanical shearing following deceleration, causing disruption and tearing of axons
- intra-cranial haematomas can be extradural, subdural or intracerebral, while contusions may occur adjacent to (coup) or contralateral (contre-coup) to the side of impact
- secondary brain injury occurs when cerebral oedema, ischaemia, infection, tonsillar or tentorial herniation exacerbates the original injury. The normal cerebral auto regulatory processes are disrupted following trauma rendering the brain more susceptible to blood flow changes and hypoxia
- the Cushings reflex (hypertension and bradycardia) often occurs late and is usually a pre terminal event

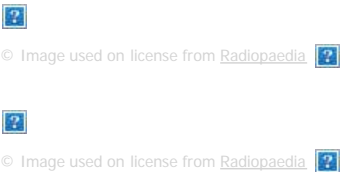

Type of injury	Notes
	Bleeding into the space between the dura mater and the skull. Often results from acceleration-deceleration trauma or a blow to the side of the head. The majority of epidural haematomas occur in the temporal region where skull fractures cause a rupture of the middle meningeal artery.
Extradural (epidural) haematoma	Features <ul style="list-style-type: none">• features of raised intracranial pressure• some patients may exhibit a lucid interval
	Bleeding into the outermost meningeal layer. Most commonly occur around the frontal and parietal lobes.
Subdural haematoma	Risk factors include old age, alcoholism and anticoagulation.
	Slower onset of symptoms than a epidural haematoma.
Subarachnoid haemorrhage	Usually occurs spontaneously in the context of a ruptured cerebral aneurysm but may be seen in association with other injuries when a patient has sustained a traumatic brain injury

Question 237 of 280

A 27-year-old woman is admitted to the Emergency Department following a road traffic accident. Primary survey reveals a right-sided haemothorax but she is haemodynamically stable. She is only responding to voice. A CT scan of her head (with contrast) is performed:

© Image used on license from Radiopaedia

What does the scan show?

	Subdural haematoma
	Subarachnoid haemorrhage
	Extradural haematoma
	Brain contusion
	Meningioma

□ Question 238 of 280

□ □

A 78-year-old male presents to the hyperacute stroke unit with a sudden onset left sided hemiparesis and which is subsequently demonstrated to represent an acute ischaemic infarct in the right middle cerebral artery territory with no haemorrhagic transformation. He was not thrombolysed due to presentation being outside the time window. As part of his stroke investigations, echocardiogram demonstrates no mural thrombus or regional wall abnormalities and an ejection fraction of 70%. The 24 hour tape recorded no arrhythmias. Carotid Dopplers demonstrate 40% stenosis in the right internal carotid artery, 55% stenosis in the left internal carotid artery. Blood pressure measured 125/75mmHg. He takes simvastatin 40mg nocte and has no known drug allergies. What would be the optimal treatment?

	Refer to vascular surgery for right carotid endarectomy
	Refer to vascular surgery for left carotid endarectomy
	300mg oral aspirin for 14 days, then clopidogrel 75mg
	Subcutaneous low molecular weight heparin, then warfarin loading
	Perindopril 4mg OD

Dashboard

Question 240 of 280

A 72 year old male is brought into A&E by ambulance after a third episode of limb jerking in 72 hours was witnessed by his wife. As you arrive, the patient becomes increasingly unresponsive and you witness small amplitude jerking of all four limbs. While the resus nurse obtains midazolam two minutes into his seizure, you note his eyes are closed tight and it is not possible to forcefully open them in order to check papillary reflexes. The amplitude of his limb jerking also become increasingly large. You note blood on his tongue and urinary incontinence. He does not suffer head or limb injury. His seizure spontaneously terminate before any medication is administered about 6 minutes after its onset. He becomes increasingly responsive about 2 minutes after the end of limb jerking and appears tearful. He is extremely apologetic for the fuss he has caused. What is the diagnosis?

	Partial seizure
	Absence seizure
	Secondary generalised seizure
	Pseudoseizure
	Myoclonic seizure

Dashboard

Question 241 of 280

□ □

A 27-year-old woman comes for review. She is having problems with increasingly frequent migraine attacks. These occur throughout her menstrual cycle and have no relation to her periods. She has tried a combination of paracetamol and ibuprofen to try and control the attacks but this seems to have had a limited effect. Her current medication includes paracetamol and ibuprofen as required and Cerazette (a progestogen-only pill).

What is the most appropriate medication to try and reduce the frequency of her migraine attacks?

	Propranolol
	Zolmitriptan
	Topiramate
	Amitriptyline
	Switch Cerazette to a combined oral contraceptive pill

Dashboard

Question 242 of 280

□ □

You are the medical registrar on call. While reviewing another patient, you notice an 82-year-old female inpatient on the same ward, currently treated for community-acquired pneumonia sitting in a chair. You notice a persistent movement of her head, in a nodding motion, associated with a tremor of both hands, worse in the left than the right. Reading through her notes, she has previously been treated for epilepsy and was started on oral phenytoin by her GP 4 months ago. On examination, the hand tremor appears to worsen when her arms are outstretched. She performs finger-nose dysmetria testing without difficulty with no speech. She demonstrates no cogwheeling. The patient appears unconcerned by the symptoms 'I have learned to live with it for years doctors!' she tells you. What is the most likely diagnosis?

	Tremor-predominant Parkinson's disease
	Phenytoin induced cerebellar tremor
	Essential tremor
	Physiological tremor
	Orthostatic tremor

Dashboard

Overall score: 0%

Question 243 of 280

A 32-year-old man had a compressive pituitary macroadenoma surgically removed in France 4 weeks ago and has been on pituitary hormone replacement since, including growth hormone. Surgery was uncomplicated and he initially made a good recovery. He has no other past medical history. He has now developed, over the last 1-2 weeks, poor balance, with a broad-based gait. He has also become extremely forgetful. On examination, he has an ataxic gait and you also observe occasional myoclonic limb movements. His MMSE score is 22/30. Clinical examination is otherwise unremarkable, as are routine blood investigations. Given the likely diagnosis, what might you expect to find on his MRI brain?

	Areas of demyelination in the cerebellum
	An area of high T2 signal in the right middle cerebral artery territory with restricted diffusion on diffusion-weighted sequences
	High T2 signal in the posterior thalamus
	Leptomeningeal enhancement
	Loss of grey-white matter differentiation

Dashboard

Question 244 of 280

□ □

A 64 year old gentleman presented to the neurology clinic for review. He had a history of motor neuron disease which had been progressing over the past five years. He had significant weakness in all of his limbs, and was dependent on a wheelchair. He took baclofen for relief of muscle spasms, and amitriptyline to reduce salivation, but was otherwise not on any medication. He mentions that in addition to his weakness continuing to progress he has been suffering from headaches in the morning. These were generalised and described as throbbing in nature. He also reported not feeling refreshed after sleep.

On examination there is generalised muscle wasting, with fasciculations in all limbs. Reflexes were absent, other than bilateral extensor plantar responses. Eye movements and fundoscopy are normal. Palatal movements were normal, and there was no significant dysphagia on swallow test.

Which intervention is most likely to confer the greatest survival benefit in this patient?

	Riluzole
	Feeding via percutaneous endoscopic gastrostomy
	Non-invasive ventilation
	Home oxygen therapy
	Prophylactic antibiotics

Dashboard

Question 245 of 280

□ □

You review an 80-year old retired teacher in your clinic. She has been complaining of numbness on her arms and difficulty walking. On examination you find she has reduced sensation lateral aspect of her arms and forearms in the anatomical position. She has no wasting on the muscles of her hands. She has reduced biceps and supinator reflexes and reduced power bilaterally.

When she gets up to go you notice she has a scissoring gait which is wide based. You ask her to close her eyes and she is unable to stand still without support.

She lives on her own and usually is independent, although recently she has been struggling to cope. She has a background of hypertension and high cholesterol.

What is the most appropriate investigation to diagnose this lady?

	Cervical myelography
	Cervical X-Ray
	Nerve conduction studies
	Nerve biopsy
	MRI of the cervical cord

Dashboard

Overall score: 0%

Question 246 of 280

□ □

A 78-year-old male with a background of atrial fibrillation, ischaemic heart disease, hypertension is brought to hospital by his wife who is concerned about a recent deterioration in his health. For the last few weeks his wife has noticed that the patient has been more unsteady on his feet which has resulted in falls around the house. His wife also informs you that the patient has been more forgetful and less interested in his hobbies than usual. When you ask the patient about his symptoms, his main concern is that he has recently developed problems with urinary incontinence which he finds embarrassing.

As part of the investigation into this patient's condition, a CT scan of the patient's head is requested. What is the most likely finding?

	Diffuse cerebral atrophy with enlargement of cortical sulci and ventricles
	A hyper-dense bi-convex extra-axial collection beneath the squamous part of the temporal bone
	Small areas of low density in the distribution of the middle cerebral artery, suggestive of old lacunar infarcts
	A concave-shaped extra-axial collection with increased attenuation
	Enlarged third and lateral ventricles, disproportionate to the enlargement of the cortical sulci

Dashboard

Question 247 of 280

□ □

A 62 year old Afro-Caribbean female is brought to the Emergency Department by husband after a 3 day history of unusual, odd behaviour at home. The family had hosted a dinner party that evening and the patient was reported to have been very disinhibited, agitated and describing hallucinations around her guests. In the past 3 weeks, she had two episodes of generalised seizures witnessed by her husband, each lasting for up to 5 minutes before spontaneously terminating, associated with urinary incontinence and tongue biting. She has no history of epilepsy and is not on any regular medications, but was diagnosed with ovarian teratoma two years ago. On examination, she has no focal neurology but you note a dystonic orofacial movement disorder. A CT head was unremarkable, with no acute infarct, haemorrhage or space occupying lesion demonstrated.

Which investigation is most likely to produce the diagnosis?

	MRI head
	Lumbar puncture
	Anti-NMDA receptor antibodies
	Anti-MuSK antibodies
	Anti-GM1 antibodies

Dashboard

□ Question 248 of 280

□ □

A 33-year-old man who has recently emigrated from Bolivia is referred to neurology after the recent onset of seizures. These are generalised in nature and are now occurring on a daily basis. His friend reports that he has been complaining of headaches recently and has also been acting out of character.

He has fit whilst leaving the outpatients department. This terminates spontaneously and he is transferred to the Emergency Department.

A CT scan is requested:

Question 249 of 280

□ □

A 36-year-old female presents to clinic with transient visual loss. She reports three episodes over the last few months where her 'turns black' in both eyes despite being alert. This lasts for a few seconds and is then followed by a unilateral throbbing headache associated with nausea and phonophobia. It is worse on exertion and lasts for a couple of days. On examination her visual acuity is 20/20 bilaterally, her visual fields are normal and fundoscopy is unremarkable.

What is the most likely diagnosis?

	Transient ischaemic attack
	Amaurosis fugax
	Anterior ischaemic optic neuropathy
	Temporal arteritis
	Migraine with aura

Question 250 of 280

□ □

A 23 year old white Caucasian left-handed male presents with a 24 hour history of slurred speech. He is a 'frequent flyer' in the Emergency Department with repeated admissions and known is a known user of intravenous drugs and alcohol. His past medical history includes depression and previously treated in adolescence for functional neurological symptoms. He denies having had a drink for the past 2 weeks but used intravenous cocaine yesterday.

On examination, he is obviously unkempt and a lack of prominent veins. There is an old abscess scar over his right femoral crease. His speech is markedly slurred but he remains orientated to time and place. You also note significant loss of forehead creasing and facial weakness on both sides of his face with normal facial sensation. In addition, his power is 4-/5 in shoulder abduction, shoulder adduction, hip flexion and hip extension, with 5/5 power on all other movements. Reflexes were present in biceps, supinator, patella and ankle, with absent triceps reflex. Both plantar reflexes were downgoing. Sensation to cotton wool, proprioception and pin prick was normal, with the patient reporting no pain.

What is the diagnosis?

	Heavy metal intoxication
	Guillain Barre syndrome
	Botulism
	Chronic inflammatory demyelinating polyneuropathy (CIDP)
	Myasthenia gravis

Dashboard

Question 251 of 280

□ □

A 48-year-old woman presented to the emergency department with a severe headache. Symptoms had started early that day while the patient had been walking around her office with the headache reaching maximal intensity within a few minutes. The pain was felt across the entirety of the patient's head and was much improved when she lay down flat. There were no associated symptoms and the patient had been constitutionally well in the preceding days.

The patient had no past medical history and was nulliparous. She was a non-smoker who consumed 15 units of alcohol per week.

Clinical examination demonstrated no evidence of focal neurological deficit and no signs of meningism. Simple analgesia given in the emergency department had limited impact on the patient's headache.

CT brain with venogram: no evidence of intra-axial or extra-axial bleeding; no space occupying lesion; no hydrocephalus; no evidence of venous sinus thrombosis

Lumbar puncture: opening pressure 5 mmHg; red cells 8 mm³; white cells 1 / mm³; no xanthochromia

What is the next best investigation to confirm the likely diagnosis?

	Digital subtraction myelography
	Cerebral angiography
	CT brain with contrast
	MRI whole spine with STIR
	MRI brain with gadolinium

Dashboard

Question 252 of 280

You have been referred a 45-year-old man by the Accident and Emergency doctors with a severe headache. The headache woke him up at 3am, and he describes it as the worst headache he's ever had. He has had two episodes like this over the past three days that have followed a very similar pattern, each lasting around 70 minutes before going. The pain is mainly around the left eye and temple and is sharp in nature. On examining him you note that his left eye is watering and swollen, and there's some redness and mild bruising just above the eye. When you ask him about this bruising he says that the pain was so bad he bashed his head against the fridge door to try and help take it away.

How would you treat his headache?

	Oral triptan
	Indometacin
	100% oxygen and indometacin
	100% oxygen
	100% oxygen and nasal triptan

Question 253 of 280

□ □

A 77-year-old female has two episodes of weakness affecting the left arm and leg each lasting ten minutes, both within the space of 2 days. She did not attend the emergency department after the first episode. Her only significant past medical history is hypertension, for which she takes amlodipine 5mg OD. She has experienced one similar episode to this one year ago but did not seek medical attention. Her daughter is present who informs you that the patient has lost a significant amount of weight in the last year. On further questioning, she reports some haemoptysis lately. Her blood pressure in the department was 170/90mmHg initially.

Her bloods reveal

Hb	11.5 g/dl
Platelets	149 * 10 ⁹ /l
WBC	13.1 * 10 ⁹ /l

Na ⁺	132 mmol/l
K ⁺	5.3 mmol/l
Creatinine	111 µmol/l
CRP	15 mg/l

ECG: Sinus tachycardia, rate 104/min

What is the most appropriate management for this lady?

	Aspirin + transient ischaemic attack (TIA) clinic referral
	Aspirin and dipyridamole + TIA clinic referral
	Aspirin and clopidogrel + TIA clinic referral
	Admit for CT head + aspirin

	Reassure and discharge

□ Question 254 of 280

A 70-year-old man with a history of hypertension and benign prostatic hypertrophy is brought in by ambulance after a fall. He reports he felt dizzy after standing up from his arm chair, stumbled and tripped over his cat. His wife, who witnessed the fall, reports that he then hit his head on the coffee table a lost consciousness for around 1 minute.

She describes no abnormal movements or incontinence. On regaining consciousness he was oriented immediately. He remembers regaining consciousness. He has no headache, dizziness, nausea or vomiting.

On examination, he has a small laceration on his forehead. His pupils were equal and reactive to light. He had no focal neurological deficits. He was a 15 on the Glasgow Coma Scale. His abbreviated mental test score was 10/10.

ECG: Sinus rhythm. 70 beats per minute. No T wave or ST segment changes.

Blood pressure (lying): 135/75 mmHg

Blood pressure (standing): 110/60 mmHg

Haemoglobin	135 g/dl
Troponin T	1 ng/L

Urine dip: trace of protein

What is the most appropriate course of action?

	Admit for CT head within 1 hour
	Admit for CT head within 8 hours
	Admit for CT head within 24 hours
	Discharge to return for CT head next day
	Discharge with outpatient follow-up, no imaging required

□ Question 256 of 280

A 46-year-old white Caucasian female presents to the Emergency Department after waking up unable to walk and complains about problems with vision in her right eye. The patient says she is normally extremely healthy and the only time she has ever visited her GP was when she had an episode of diarrhoea and vomiting about a week ago. She is understandably distressed as she has not experienced any symptoms before and has not been previously diagnosed with any medical conditions. She has no drug or family history. Nursing staff report to you that she has been given a pad on her bed as she is incontinent of urine, which she is tearfully embarrassed by.

On examination of her cranial nerves, a right relative afferent papillary defect is noted. Visual acuity and colour vision are 6/6 with 17/17 Ishihara plates on the left, 6/60 with 0/17 Ishihara plates on the right. She reports no diplopia with a full range of eye movements and normal facial sensation. Facial movements are normal. Fundoscopy was unremarkable. Examination of the patient's upper and lower limb power demonstrated normal tone with 2-/5 power on the left arm and leg in all movements; and 4-/5 all movements in right arm and leg. There is a patchy loss of sensation to cotton wool on right lateral wrist and anterior aspect left lateral shin. Both plantars are upgoing. Reflexes are brisk at knee and ankles bilaterally. Anal tone and saddle sensation are intact. The patient's cognitive state is normal on superficial examination.

An urgent MRI head and whole spine demonstrates abnormal high signal in the cervical cord from C3 to C7. Her blood tests were mislabelled and hence unavailable. A lumbar puncture was performed with the following results:

WCC	12 mm/ ³
RBC	<1 mm/ ³
Protein	0.9 g/l
Glucose	5.2 mmol/l (10.2 mmol/l serum)
Oligoclonal bands	awaited
Viral PCR	awaited

What is the most likely diagnosis?

	Idiopathic intracranial hypertension
	Transverse myelitis

	Miller-Fisher syndrome
	Multiple sclerosis
	Devic's disease

Dashboard

Question 257 of 280

A 45-year-old male presents with ascending weakness. He first noticed that he was tripping over more easily, but now has trouble getting out of a chair. He feels otherwise well. Of note, he did have moderate diarrhoea which had completely resolved a week prior to developing this weakness.

On examination, he is haemodynamically stable with a heart rate of 68 beats per minute and a blood pressure of 135/80 mmHg. His respiratory rate is 18 breaths per minute. He has reduced power in ankle plantar and dorsiflexion bilaterally, absent ankle jerks and reduced knee jerks. His plantar responses are downwards.

Acutely, which of the following results will most assist you with a diagnosis?

	MRI showing inflammation of the lumbo-sacral spinal cord
	Elevated white cell count on cerebrospinal fluid (CSF) analysis
	Abnormal nerve conduction tests of the lower limbs
	Elevated CSF protein
	Raised erythrocyte sedimentation rate (ESR)

Dashboard

Overall score: 0%

Question 258 of 280

□ □

A 47-year-old man is admitted to the Medical Assessment Unit with a pneumonia. He has had a cough for the last week which has not settled with amoxicillin from his GP.

His past medical history includes alcoholic liver disease with a hepatic transplant 6 months previously, hypertension and diet-controlled type II diabetes. He has remained abstinent from alcohol for the last 18 months and is a lifelong non-smoker. His medications are ramipril, simvastatin and tacrolimus.

On admission he has a temperature of 38.1 °C and oxygen saturations of 94% on air. His heart rate is 110 beats per minute and blood pressure is 105/65 mmHg. On auscultation he has left basal crepitations and chest x-ray confirms a left lower lobe pneumonia.

He is started on intravenous fluids, 2 litres oxygen via nasal cannulae, co-amoxiclav and clarithromycin. His statin is withheld.

2 days later, the ward team are asked to review the patient as he has developed limb twitching. During the assessment he has a generalised tonic-clonic seizure which requires lorazepam to terminate it.

Which investigation is most likely to reveal the cause for his seizures?

	Blood cultures
	CT head
	Electrolytes
	Lumbar puncture
	Tacrolimus level

Overall score: **0%**

Question 260 of 280

A 58-year-old male is brought into your outpatient clinic by his wife. The patient does not understand why he needs to see a doctor and just wants to get back to work. However, she reports a rather vague history of increasing withdrawal from social interactions and odd repetition of 'catch phrases' over the past 9 months. In addition, she feels his behaviour has changed and is very inappropriate when meeting up with friends, once urinating at the table while having dinner. Last week, he gave her a grave headstone for her birthday, saying 'it is nice to be well-prepared!' While she was understandably upset, he was mystified as to why his well thought out gift might have caused distress. On examination, he continues to repeat the phrase 'Whats up doc?!' at a regular interval, disturbing your history taking. You finally complete a mini-mental test examination, scoring 27/30. What is the most likely diagnosis?

	No medical diagnosis
	Borderline personality disorder
	Bipolar disorder
	Schizophrenia
	Frontotemporal dementia

Question 261 of 280

□ □

A previously well 69 year old patient presents to the A+E department with a sudden onset of weakness. This was noticed by his wife who immediately called 999.

Neurological examination:

CN I-IV normal

CN V ophthalmic and maxillary divisions normal with reduced sensation in mandibular division on left side

CN VI normal

CN VII reduced power to left lower facial musculature

CN VIII normal

CN IX, X and XII weakness in swallow

CN XI weakness on turning the head to the left.

Right upper limb normal tone, power 5/5, normal reflexes and sensation. Normal finger pointing.

Left upper limb markedly increased tone, power 1/5 globally in all muscle groups, brisk reflexes and reduced sensation to light touch. Unable to move limb to determine ability to finger pointing.

Right lower limb normal tone, power 5/5, normal reflexes and sensation. Heel-knee-shin test normal.

Left lower limb slightly increased tone, power 3/5 globally, brisk reflexes and reduced sensations. Reduced ability to heel-knee-shin test when compared to right side.

Gait - not assessed due to weakness.

Romberg's test - not done due to weakness.

	Left middle cerebral artery
	Right middle cerebral artery

□ Question 262 of 280

□ □

A 33-year-old woman presents to the Emergency Department with a severe headache. She describes falling to the ground whilst walking to work and since having a severe occipital headache. Her GCS is 15/15 and her vital signs are stable, other than a low grade pyrexia of 37.5°C. Her headache fails to improve with analgesia and a CT head with contrast is performed:

© Image used on license from Radiopaedia

What does the scan show?

--	--

	Extradural haematoma
	Brain contusion
	Subdural haematoma
	Meningioma
	Subarachnoid haemorrhage

□ Question 263 of 280

□ □

A 27 year-old woman attends the neurology clinic complaining of headache and visual disturbance. She has recently immigrated from Ghana. Her symptoms began approximately one month ago, shortly after the birth of her first child. She experiences dull frontal headache which is worst in the mornings and on coughing or straining, as well as transient episodes of 'darkening' of her vision. She saw a doctor in Ghana and was diagnosed with idiopathic intracranial hypertension. She is taking acetazolamide 250mg BD and no other medication.

On examination the visual fields are markedly constricted and the right blind spot is enlarged. Fundoscopy shows bilateral papilloedema worse on the right. The remainder of the neurological examination is unremarkable. BMI is 18 kg/m².

Plain computed tomography of the brain is normal.

Incidentally as she is leaving the clinic she mentions that she has also been experiencing pins and needles in the hands and feet.

What is the best course of action?

	Increase dose of acetazolamide
	Request nerve conduction studies
	Organise for therapeutic lumbar puncture
	Refer to neurosurgeons for consideration of ventriculo-peritoneal shunting
	Request CT venography

Dashboard

Question 264 of 280

□ □

A 32 year old female is seen in neurology clinic due to a 4 month history of headaches. She described having headaches most days on waking up, which were throbbing in nature. She found that they eased off after mobilising, and that coughing made them worse. She reported a couple of episodes of blurred vision on waking, but no nausea or vomiting. Her general practitioner arranged for an outpatient magnetic resonance head scan which was normal. Her body mass index (BMI) had been 27 kg/m², but on advice from her general practitioner she had lost weight, and her BMI was now 23 kg/m². She was not on any regular medications, other than paracetamol and ibuprofen which she had been using regularly for her headaches.

There was no focal neurological deficit on examination, and her visual acuity was normal. On fundoscopy there was a mild degree of papilloedema. Blood pressure was 125/82mmHg. Blood tests were unremarkable.

What is the most appropriate next step in management?

	Lumbar-peritoneal shunt
	Optic nerve fenestration
	Cessation of paracetamol and ibuprofen
	Acetazolamide
	Sumatriptan

Dashboard

□ Question 268 of 280

A 57 year old male presents with a 3 months history of increasing clumsiness in his hands and arms. He has a complicated past medical history: 22 years ago, he underwent a renal transplant after progressive deterioration in his renal function following diagnosis with autosomal dominant polycystic kidney disease aged 25. His transplant has functioned well since but the patient has since undergone two resections of squamous cell carcinomas and one serious lengthy hospital admission for a systemic fungal infection. He stopped working a year ago as a wine merchant, after complaining that he was no longer able to differentiate 'the smells of his wines as he got older'.

On examination, he is alert and orientated. Questioning was challenging due to his hearing impairment, despite bilateral hearing aids. He scored 17/30 on a mini-mental examination. Pupils were reactive with a full range of eye movements. Facial power and sensation were normal, with symmetrical palatal elevation and no tongue deviation. He was profoundly deaf bilaterally. Tone, power and sensation were normal, reflexes were present with downgoing plantars. However, you note significant bilateral finger-nose dysmetria and heel-shin malco-ordination.

Which investigation is likely to produce the unifying diagnosis?

	Lumbar puncture for cerebrospinal fluid including 14-3-3, S100
	EEG
	MRI head
	Neurogenetic testing
	Nerve conduction studies and EMG

Dashboard

Question 269 of 280

□ □

A 67 year-old woman presents to hospital after a collapse at home. One week earlier she had seen her own doctor after feeling generally unwell with fever, myalgia, and coryza. These symptoms were attributed to a viral infection and have now resolved. However, for the past few days she has felt unsteady on her feet and has had to hold on to the furniture whilst walking around the house. For the last two days in particular she has also noticed that her vision has deteriorated, and she has been seeing double. Today she tried to hold onto the sofa whilst walking around the room, but misjudged the distance and lost her grip, causing her to fall to the floor. Her daughter who is also present adds that she feels her mothers speech is slurred compared to normal, and has been so for the past three days.

Her past medical history includes hypertension, hypothyroidism, type 2 diabetes, hyperlipidaemia, angina, and recurrent urinary tract infection. She takes ramipril, amlodipine, doxazosin, levothyroxine, metformin, gliclazide, simvastatin, atenolol, nicorandil, and nitrofurantoin. She does not smoke but admits to enjoying a glass of sherry on most nights. Usually she is independently mobile, without aids. She lives on her own and is self-caring.

On examination, there are some bruises on the left shoulder where she fell, but no suggestion of any fracture. Observations are normal and she is afebrile. Cardiovascular, respiratory, and abdominal examination is unremarkable. She is fully alert and oriented. Pupils are equal and reactive to light. Eye movements are grossly impaired in all directions. There is no facial asymmetry. Muscle power is normal in all limbs, but finger-nose pointing is impaired and she is unable to walk in a straight line. Reflexes are unobtainable. Sensation is normal.

What is the most likely diagnosis?

	Wernickes encephalopathy
	Viral cerebellitis
	Myasthenia gravis
	Miller Fisher syndrome
	Posterior circulation stroke

Overall score: **0%**

□ Question 270 of 280

A 78-year-old male presents with a one-year history of progressive unsteadiness on walking. He had previously been extremely fit and healthy, walking around 2 miles to the shops every day and only retired as a publicist 3 years ago. He underwent radiotherapy for localised squamous cell carcinoma of his vocal cords 18 months ago but otherwise had no other past medical history. He admits to having drunk 'more than he should have' while working in the city but says he has since cut down to moderate levels. He stopped smoking 5 years ago, with a 30 pack year history. Over the past 3 months, he has become incontinent of urine and has to rely on pads, which he is greatly embarrassed by.

On examination, he has a shuffling gait in his lower limbs with good arm swing. He is markedly slowed and takes 120 seconds to walk 20 metres. He turns around 180 degrees in 6 steps with no resting tremor, rigidity or bradykinesia. Examination of his tone, power, sensation, coordination and reflexes are all unremarkable. His voice is quiet and whispering. His cranial nerves are normal with a full range of eye movements. An abbreviated mental test scores 9/10, a Montreal cognitive assessment (MOCA) scored 29/30. His initial blood tests are as follows:

Hb	94 g/l
MCV	103.3 fl
Platelets	$232 \times 10^9/l$
WBC	$6.3 \times 10^9/l$

Na ⁺	139 mmol/l
K ⁺	4.9 mmol/l
Urea	7.5 mmol/l
Creatinine	98 μ mol/l
CRP	2 mg/l
Vitamin B12	327ng/l
Folate	5.2 nmol/l

An MRI head is performed, demonstrating diffuse mild microangiopathic changes with prominently dilated lateral and

third ventricles. No intracranial masses are noted. You perform a lumbar puncture, with the patient lying in the left lateral position using a 22G spinal needle and obtain cerebrospinal fluid with the first pass. His opening pressure is 16.6 cmH2O. What is the most appropriate course of action?

	Remove 30mls cerebrospinal fluid and refer to neurosurgeons
	Prescribe urgent intravenous pabrinex
	Urgent urological referral for urodynamic studies +/- flexible cystoscopy
	Prescribe Sinemet 250 with anti-emetic and re-measure walking time
	Urgent CT angiography and prescribe aspirin 300mg

Question 271 of 280

A 46 year-old man is admitted to hospital after he is found wandering the streets, unable to remember who he is or how he got there. After a collateral history is obtained, he is referred to the neurologists for further investigation.

Over the last two months he has become increasingly forgetful and clumsy, and his behaviour has become progressively more bizarre. His speech has become confused, and he struggles with daily tasks. Others have commented that he has become very 'twitchy', and he sometimes drops things out of his hands without meaning to.

He was previously fit and well and the main carer for his father who suffers from motor neuron disease. His sister who previously helped him care for their father was recently killed in a car accident.

His only past medical history is that at age 22 he underwent extensive surgical resection of a large parafalcine meningioma which was discovered after investigation of chronic headache. Since the operation he has been free of headache.

On examination he is completely disoriented in time, place, and person. His gait is broad-based and uncoordinated, and during the examination you notice several shock-like jerks of his arms. Tone, power, reflexes, and sensation are otherwise normal, and cranial nerve examination is unremarkable.

What is the most likely diagnosis?

<input type="checkbox"/>	Viral encephalitis
<input type="checkbox"/>	Creutzfeld-Jakob disease
<input type="checkbox"/>	Frontotemporal dementia
<input type="checkbox"/>	Alzheimer's disease
<input type="checkbox"/>	Dissociative fugue

Overall score: **0%**

Question 272 of 280

□ □

A 42-year-old man presented with a partial left Horner's syndrome (ptosis with miosis, no anhidrosis), ipsilateral neck pain and reduced visual acuity on the same side.

He reported that the first symptom was neck pain and that his vision worsened over the next two hours. On admission, his blood pressure was 145/80 mmHg and heart rate was 80 beats per minute in sinus rhythm. His chest was clear.

His initial non-contrast enhanced CT brain scan showed a very small area of gliosis in the left frontal area possibly related to a distant injury, but no acute pathology.

Which of the following tests is likely to give you a diagnosis?

	MRI of the brain
	CT carotid angiogram
	Chest X-Ray
	Erythrocyte sedimentation rate (ESR) and temporal artery biopsy
	CT venogram of the neck and brain

Question 273 of 280

□ □

A 73 year old gentleman is admitted to the medical assessment unit with a fall. A collateral history from his wife reveals that he has been having frequent falls (nearly 2-3 times a week) for the last 4 months. This has resulted in multiple admissions where a chest infection is thought to be the main cause for his deterioration. His wife also states he is having problems swallowing, chokes on his food frequently and has not been himself recently with frequent bouts of aggression. On examination you note the patient has an expressionless face, and kyphosed posture and mild tremor bilaterally. He has cogwheeling of both upper limbs. Examination of his legs is unremarkable. On inspection of his gait, it appears parkinsonian in character, but you stop him only after a few steps as he seems unsteady. On cranial nerve examination you note he has difficulty following your finger downwards but the remainder of the cranial nerve examination is normal. Given these features, what is the most likely underlying diagnosis?

	Multiple system atrophy
	Idiopathic Parkinsons disease
	Progressive supranuclear palsy
	Vascular Parkinsonism
	Lewy body dementia

□ Question 274 of 280

An urgent medical consult was requested regarding a 52-year-old female who had been admitted to the neurology ward a few hours previously and who had developed hypotension. She had presented to the Emergency Department with new weakness in her legs that had occurred over a course of three days. She also complained of continual lower back pain and pain in the top of her thighs, and as her illness progressed she was no longer able to weight bear. She had a past medical history of hypothyroidism, for which she was prescribed levothyroxine 125mcg OD, and other than an episode of viral gastroenteritis diagnosed by her GP two weeks prior to her current admission she was fit and well. Upon transfer to the neurology ward blood investigations, a chest x-ray, CT head scan and lumbar puncture were performed, the results of which are as follows:

Hb	132 g/l
Platelets	248 * 10 ⁹ /l
WBC	8.2 * 10 ⁹ /l

Na ⁺	138 mmol/l
K ⁺	5.2 mmol/l
Urea	6.4 mmol/l
Creatinine	77 µmol/l
CRP	15 mg/l
Glucose	7.2 mmol/l
TSH 0.26	(NR 0.4-3.6 mu/l)
Free T4 10.6	(NR 10 - 20 pmol/L)

Autoantibody screen: awaiting results

Urinalysis: negative

Urine MCS: awaiting results

Blood MCS: awaiting results

Chest x-ray: normal appearances of heart and lung fields
CT head: normal intracranial appearances

Lumbar puncture:

Protein	0.8g (NR 0.2-0.4 g/L)
Glucose	6.3 (blood glucose 7.2)
WCC 8	(<5/mm ³)
Opening pressure	15 (NR 10-20 cmH2O)
Microscopy	nil seen, awaiting culture and sensitivity result

Whilst awaiting definitive measurement her blood pressure was noted to fluctuate between 55/30 mmHg and 162/84 mmHg within a matter of minutes; at present her blood pressure was 62/42 mmHg. Upon examination of her cardiovascular system, she was clinically well perfused with a normal and palpable radial pulse, a JVP of 3cm and a peripheral and central capillary refill time of less than two seconds. He heart rate was 82 bpm. Examination of her respiratory system was unremarkable with no respiratory distress, a respiratory rate of 16/min and oxygen saturations of 99% on air. Examination of her gastrointestinal system was unremarkable. Examination of her peripheral nervous system revealed a power deficit of grade 2/5 in all muscle groups of the lower limbs, power 5/5 in the upper limbs and normal sensation and coordination throughout. Knee and ankle reflexes were absent bilaterally. Cranial nerve examination was unremarkable.

What is single next best step with regards to management of her blood pressure?

	Commence dobutamine infusion
	Commence noradrenaline infusion
	Commence intravenous fluid resuscitation with 500ml of colloid stat
	Commence intravenous immunoglobulin
	Arrange urgent plasmapheresis

An urgent medical consult was requested regarding a 52-year-old female who had been admitted to the neurology ward a few hours previously and who had developed hypotension. She had presented to the Emergency Department with new weakness in her legs that had occurred over a course of three days. She also complained of continual lower back pain and pain in the top of her thighs, and as her illness progressed she was no longer able to weight bear. She had a past medical history of hypothyroidism, for which she was prescribed levothyroxine 125mcg OD, and other than an episode of viral gastroenteritis diagnosed by her GP two weeks prior to her current admission she was fit and well. Upon transfer to the neurology ward blood investigations, a chest x-ray, CT head scan and lumbar puncture were performed, the results of which are as follows:

Hb	132 g/l
Platelets	248 * 10 ⁹ /l
WBC	8.2 * 10 ⁹ /l

Na ⁺	138 mmol/l
K ⁺	5.2 mmol/l
Urea	6.4 mmol/l
Creatinine	77 µmol/l
CRP	15 mg/l
Glucose	7.2 mmol/l
TSH 0.26	(NR 0.4-3.6 mu/l)
Free T4 10.6	(NR 10 - 20 pmol/L)

Autoantibody screen: awaiting results

Urinalysis: negative

Urine MCS: awaiting results

Blood MCS: awaiting results

Chest x-ray: normal appearances of heart and lung fields
CT head: normal intracranial appearances

Lumbar puncture:

Protein	0.8g (NR 0.2-0.4 g/L)
Glucose	6.3 (blood glucose 7.2)
WCC 8	(<5/mm ³)
Opening pressure	15 (NR 10-20 cmH2O)
Microscopy	nil seen, awaiting culture and sensitivity result

Whilst awaiting definitive measurement her blood pressure was noted to fluctuate between 55/30 mmHg and 162/84 mmHg within a matter of minutes; at present her blood pressure was 62/42 mmHg. Upon examination of her cardiovascular system, she was clinically well perfused with a normal and palpable radial pulse, a JVP of 3cm and a peripheral and central capillary refill time of less than two seconds. He heart rate was 82 bpm. Examination of her respiratory system was unremarkable with no respiratory distress, a respiratory rate of 16/min and oxygen saturations of 99% on air. Examination of her gastrointestinal system was unremarkable. Examination of her peripheral nervous system revealed a power deficit of grade 2/5 in all muscle groups of the lower limbs, power 5/5 in the upper limbs and normal sensation and coordination throughout. Knee and ankle reflexes were absent bilaterally. Cranial nerve examination was unremarkable.

What is single next best step with regards to management of her blood pressure?

	Commence dobutamine infusion
	Commence noradrenaline infusion
	Commence intravenous fluid resuscitation with 500ml of colloid stat
	Commence intravenous immunoglobulin
	Arrange urgent plasmapheresis

□ Question 275 of 280

□ □

A 22-year-old male is referred to clinic by his GP. His initial complaint had been that his friends have been increasingly remarking on how his eyelids look increasing 'droopy' over the past 9 months. He denies any diplopia or muscle weakness. He has no past medical history, is a non-smoker and non-drinker. On examination, you note bilateral inability to abduct or adduct his eyes. Vertical gaze is also inconsistently impaired. His upper and lower limb neurological investigation was unremarkable except very mild finger-nose dysmetria, his bloods tests show no abnormalities. His ECG demonstrates sinus rhythm with a PR interval of 260ms. Fundoscopy reveals a pigmented retina. What is the diagnosis?

	Myasthenia gravis
	Thyroid eye disease
	Oculopharyngeal muscular dystrophy
	Extraocular muscle fibrosis
	Kearns-Sayre syndrome

Question 276 of 280

A 68-year-old man who has a history of Type 2 diabetes for the past 12 years comes to the clinic for review. His diabetes is currently managed with BD mixed insulin and over the past year he has suffered increasing pins and needles and pain in both feet. Apart from Type 2 diabetes, a previous myocardial infarction and intermittent urinary retention over the past year are noted. His GP has diagnosed him with benign prostatic hypertrophy. Examination reveals a blood pressure of 148/82 mmHg, her pulse is 80 beats per minute and regular. There is peripheral neuropathy affecting both feet, which are numb to just below the ankle. Routine bloods including renal function are unremarkable.

Which of the following is the most appropriate intervention?

	Amitriptyline
	Carbamazepine
	Duloxetine
	Pregabalin
	Tramadol

Question 277 of 280

A 62-year-old male presents to the emergency department via blue light ambulance 90 minutes after sudden onset right sided weakness, expressive and receptive dysphasia. He is known to be T2DM, hypertensive on 3 agents and has a 40 pack year smoking history. On examination, you demonstrate a dense 0 out of 5 right hemiparesis. The patient has a complete expressive and receptive dysphasia, which you confirm to be new following a collateral history from his wife. The patient scores an NIHSS score of 7. He has no history of any recent surgery or head trauma. He is not on an anticoagulant and has no past medical history of coagulation disorders. His CT head demonstrates no areas of haemorrhage and a likely evolving area of ischaemic in the left middle cerebral artery territory. The radiologist calculated his ASPECT score to be 8. His observations on arrival are: temperature 36.7 degrees, heart rate 90/min and regular, blood pressure 220/150 mmHg, sats 99% on air, respiratory rate 20/min. What is the most appropriate first-line treatment?

	IV thrombolysis
	Aspirin 300mg OD
	PO amlodipine 2.5mg
	MRI head with diffusion weighting sequences
	IV labetalol

Question 278 of 280

A 23 year old investment banking intern presents to the urgent care centre complaining of progressive unsteadiness on walking over the past 6 months. He has no past medical history except type 2 diabetes, which is diet controlled, diagnosed one year ago. He has no family history of any diseases. He has been working very long hours for the past 2 years and reports high levels of stress at work, coupled a culture of 'binge-drinking' to team bond after work. Over the past 3 months, he has noticed a lack of articulation with his speech, which he assumed was secondary to alcohol. He estimates he drinks up to 30 units of alcohol a week. On examination, his cardiovascular, respiratory and abdominal systems are unremarkable. His finger-nose test is impaired bilaterally and is unable to tandem walk. He denies any neck stiffness or headache. He has a full range of eye movements. He has absent reflexes in his lower limbs and upgoing plantars bilaterally. Which investigation will provide the definitive diagnosis?

	MRI head with gadolinium contrast
	CT angiography including posterior vessels
	Lumbar puncture
	Serum genetic testing
	Muscle biopsy

□ Question 279 of 280

A 45 year old male presented with right shoulder pain and weakness. Three weeks ago he had been brought to the emergency department (ER) with the same complaint. The pain was so severe that it awoke him from sleep. At that time he took two paracetamol tablets but that gave him no relief. Eventually the ER team had been forced to give him morphine to relieve his agony having tried less potent analgesia. On further questioning he described the pain as sharp, exacerbated by movement of the shoulder, with numbness at the shoulder tip.

On examination, he was holding his right arm with his left one in adduction and internal rotation. Wasting of the deltoid muscle had been noted. The biceps tendon jerk was absent. Sensations were intact except in a small region over deltoid muscle. Lower limb examination was normal.

One month ago he had a flu. The past medical history was otherwise of no significance.

He admitted to drinking alcohol at least four times a week. He has a ten year old son who is an insulin dependent diabetic.

The following investigations were ordered:

Hb	14 g/dl
Platelets	$180 \times 10^9/l$
WBC	$6 \times 10^9/l$
MCV	85 fl
MCH	0.6 fmol/cell
MCHC	21 mmol/l
Na ⁺	135 mmol/l
K ⁺	4 mmol/l
Creatinine	85 μ mol/l
Urea	3.2 mmol/l
ESR	4 mm/hr

ANA	negative
-----	----------

What is the most likely diagnosis?

	Syringomyelia
	Brachial neuritis
	Adhesive capsulitis
	Polymyalgia rheumatica
	Cervical radiculopathy

Dashboard

□ Question 2 of 57

A 65-year-old male with a 60 pack year smoking history has been diagnosed with small cell lung cancer. He is currently undergoing chemotherapy. Over the last few months, he has noticed his vision deteriorating and complains of diplopia. He also feels weaker in his upper limbs although his symptoms do fluctuate.

On examination, he has mild ptosis of the eyelids bilaterally and a complex ophthalmoparesis affecting both eyes. He also has reduced power proximally in the upper limbs.

In this clinical syndrome, in addition to electrophysiological studies, which of the following blood test results is likely to assist with the diagnosis?

	Presence of anti-muscle specific kinase antibodies
	Presence of anti-neuronal antibodies
	Presence of voltage gated potassium channel antibodies
	Presence of sodium channel antibodies
	Presence of voltage gated calcium channel antibodies

Question 6 of 57

A 72-year-old man presents to the emergency department with shortness of breath. He describes his breathlessness has progressively become worse over the last two weeks and is especially troublesome when leaning forward. His wife has commented that his appearance has changed too, with his face becoming more swollen and different in colour. He has a past medical history of right-sided heart failure, myocardial infarction, type two diabetes, COPD and small cell lung cancer diagnosed three months ago. He is an ex-smoker of 20 pack-years and drinks moderate amounts of alcohol.

On examination, he appears settled at rest. His face is swollen and slightly purple. His neck veins are distended and his JVP is markedly elevated to 4cm. Auscultation reveals bibasal crepitations. There is pitting oedema at the ankles. A chest X-ray demonstrates a widened mediastinum. What investigation is most appropriate to establish the diagnosis?

	ECG
	Trans-thoracic echocardiogram
	Trans-oesophageal echocardiogram
	Bronchoscopy
	CT chest

□ Question 7 of 57

A 72-year-old man is referred to the oncology team after presenting to the emergency department. The patient reports progressive lower thoracic back pain over the past three weeks. The pain had now reached an intensity that had prevented him from sleeping during the past two nights, despite over the counter analgesics. The patient reported that coughing caused a severe exacerbation of the pain, but denied radiation of the pain. The patient had previously suffered mild lower back pain after exercise, but could recall no episodes that compared in intensity to his present symptoms.

The patient's wife reported she felt the patient had been unsteady on his feet over the past few days, and reported that he had nearly fallen on several occasions. The patient denied any history of sphincter disturbance or sensory symptoms. On direct questioning, the patient revealed that he had been troubled by a severe cough over the past two months and had also lost 7 kilograms in weight. He denied any history of fevers or night sweats.

The patient had an unremarkable past medical history and took no regular medications. He was a retired builder, who had stopped smoking when he took retirement seven years previously.

Peripheral nerve examination of upper limbs: normal tone, normal power, normal coordination, normal sensation, reflexes intact and symmetrical.

Peripheral nerve examination of lower limbs: tone generally increased bilaterally with 5 beats of clonus in left lower limb; power generally slightly reduced (4+/5) bilaterally, although patient limited by back pain; normal coordination; light touch sensation reduced to mid-point between symphysis pubis and umbilicus; knee and ankle jerks brisk bilaterally, plantar response up-going in left lower limb.

Respiratory examination: borderline clubbing of fingers; reduced resonance and air entry in left upper zone.

Musculoskeletal examination: point tenderness in midline of back around level of T11 / T12 vertebrae.

What is the appropriate investigation of patient's back pain?

	MRI whole-spine within 24 hours
	MRI lumbar-thoracic spine within 24 hours
	CT lumbar-thoracic spine within 24 hours

	MRI whole-spine within 7 days
	CT myelography within 7 days

□ Question 7 of 57

A 72-year-old man is referred to the oncology team after presenting to the emergency department. The patient reports progressive lower thoracic back pain over the past three weeks. The pain had now reached an intensity that had prevented him from sleeping during the past two nights, despite over the counter analgesics. The patient reported that coughing caused a severe exacerbation of the pain, but denied radiation of the pain. The patient had previously suffered mild lower back pain after exercise, but could recall no episodes that compared in intensity to his present symptoms.

The patient's wife reported she felt the patient had been unsteady on his feet over the past few days, and reported that he had nearly fallen on several occasions. The patient denied any history of sphincter disturbance or sensory symptoms. On direct questioning, the patient revealed that he had been troubled by a severe cough over the past two months and had also lost 7 kilograms in weight. He denied any history of fevers or night sweats.

The patient had an unremarkable past medical history and took no regular medications. He was a retired builder, who had stopped smoking when he took retirement seven years previously.

Peripheral nerve examination of upper limbs: normal tone, normal power, normal coordination, normal sensation, reflexes intact and symmetrical.

Peripheral nerve examination of lower limbs: tone generally increased bilaterally with 5 beats of clonus in left lower limb; power generally slightly reduced (4+/5) bilaterally, although patient limited by back pain; normal coordination; light touch sensation reduced to mid-point between symphysis pubis and umbilicus; knee and ankle jerks brisk bilaterally, plantar response up-going in left lower limb.

Respiratory examination: borderline clubbing of fingers; reduced resonance and air entry in left upper zone.

Musculoskeletal examination: point tenderness in midline of back around level of T11 / T12 vertebrae.

What is the appropriate investigation of patient's back pain?

	MRI whole-spine within 24 hours
	MRI lumbar-thoracic spine within 24 hours
	CT lumbar-thoracic spine within 24 hours

	MRI whole-spine within 7 days
	CT myelography within 7 days

Dashboard

Overall score: **0%**

Question 7 of 57

A 72-year-old man is referred with progressive lower thoracic back pain that has prevented him from sleeping. He has a long history of smoking and coughing caused a severe emphysema. He has mild lower back pain after exertion.

The patient's wife reported that he had nearly fallen on several occasions. On direct questioning, the patient had also lost 7 kilograms in the last 6 months.

The patient had an unremarkable medical history and had stopped smoking when he took retirement seven years previously.

Peripheral nerve examination of upper limbs: normal tone, normal power, normal coordination, normal sensation, reflexes intact and symmetrical.

Peripheral nerve examination of lower limbs: tone generally increased bilaterally with 5 beats of clonus in left lower limb; power generally slightly reduced (4+/5) bilaterally, although patient limited by back pain; normal coordination; light touch sensation reduced to mid-point between symphysis pubis and umbilicus; knee and ankle jerks brisk bilaterally, plantar response up-going in left lower limb.

Respiratory examination: borderline clubbing of fingers; reduced resonance and air entry in left upper zone.

Musculoskeletal examination: point tenderness in midline of back around level of T11 / T12 vertebrae.

What is the appropriate investigation of patient's back pain?

Motor and descending (efferent) pathways (red)

Pyramidal tracts

- Lateral corticospinal tract
- Anterior corticospinal tract

Extrapyramidal Tracts

- Rubrospinal tract
- Reticulospinal tracts
- Olivospinal tract
- Vestibulospinal tract

MRI whole-spine within 24 hours

MRI lumbar-thoracic spine within 24 hours

CT lumbar-thoracic spine within 24 hours

	MRI whole-spine within 7 days
	CT myelography within 7 days

□ Question 8 of 57

A medical consult was sought from the nursing staff concerning a 68-year-old gentleman admitted with a urinary tract infection. He was diagnosed with terminal adenocarcinoma of the pancreas six months ago. He had complained of increasing severe abdominal pain for the last few weeks for which his GP commenced and then titrated morphine sulphate tablets (MST) achieving a temporary analgesic effect with each increment. By the time of admission he had been using 150mg BD and was unable to tolerate any further dose increases owing to drowsiness.

His drug history comprised of ciprofloxacin 250mg BD started four days ago for the management of urinary tract infection, paracetamol 1g QDS, tramadol 100mg QDS, MST 150mg BD, senna 2 tabs ON & Movicol one sachet BD.

In view of the continuing abdominal pain investigations were organised by the inpatient team revealing the following findings:

Hb	135 g/l
Platelets	224 * 10 ⁹ /l
WBC	11.2 * 10 ⁹ /l

Bilirubin	23 µmol/l
ALP	189 u/l
ALT	326 u/l
γGT	178 u/l
Albumin	34 g/l

Chest x-ray: Normal heart borders and lung fields, no evidence of subdiaphragmatic air.

Abdominal x-ray: presence of faeces, no evidence of dilatation.

USS abdomen: multiple hypoechoic lesions within the liver, nil else abnormal noted.

What is the next most appropriate management option?

--	--

	Commence syringe driver containing diamorphine
	Refer for immediate surgical consult
	Refer for palliative radiotherapy
	Convert MST to fentanyl
	Commence trial with dexamethasone

Dashboard

Overall score: 0%

Question 9 of 57

□ □

A 54-year-old woman presents to the emergency department. She has noticed a sore throat over the last 24 hours and checked her temperature and found it to be 38.2°C. Her other observations are all normal. She has had no other symptoms and specifically denies coughing, chest pain, dysuria and diarrhoea. She is currently undergoing chemotherapy for breast cancer having last had treatment six days ago. What is the most appropriate treatment?

	Confirm neutropenia before treatment
	IV co-amoxiclav and oral clarithromycin
	Oral metronidazole
	IV piperacillin with tazobactam
	IV gentamicin

□ Question 10 of 57

A 60-year-old woman presented to the emergency department with recurrent episodes of severe headache and vomiting over past 3-4 days. She was known to have underlying metastatic breast cancer for which she was receiving palliative chemotherapy. She was also known to have underlying type 2 diabetes mellitus and osteoarthritis of bilateral knee joints.

On examination, her pulse rate was 105/min, respiratory rate was 16/min, blood pressure was 120/80 mmHg. Fundoscopy revealed early papilloedema.

A contrast enhanced CT brain was done which showed a solitary mass of 3 cm in the left cerebral hemisphere.

What is the next appropriate management?

	Start 16 mg of i.v dexamethasone and prophylactic anticonvulsants
	Start 16 mg of dexamethasone and arrange urgent MRI brain
	Refer to neurosurgery for biopsy of the brain lesion
	Refer to radiation oncologist for Whole brain radiotherapy
	Stereotactic radiosurgery

□ Question 12 of 57

You are asked to review a 67-year-old gentleman who was admitted to the medical emergency unit with pneumonia. He had been diagnosed with terminal small cell cancer of the lung which had extensively metastasised to his liver, thoracic vertebrae and femur bones. His past medical history was comprised of ischaemic heart disease, hypertension, hypercholesterolaemia and COPD.

His main complaint was of progressively worsening pain in his spine and legs. This was particularly bothersome at night; a trial of bisphosphonate therapy and radiotherapy did not provide any symptomatic relief. He was commenced initially on oral morphine sulphate solution which was converted to morphine sulphate tablets (MST); he had been on 60mg BD but this was titrated by the palliative care community nurse to 70mg BD a couple of days prior to admission with excellent analgesic effect. He was also using Oramorph solution 10mg on average 5-6 times a day for breakthrough pain.

He had been accordingly treated with intravenous antibiotics whilst on the ward making a full recovery. Prior to discharge, he was very keen on commencing transdermal treatment so as to minimise the number of oral medications taken.

What is the most appropriate starting dose to commence, with a view to completely discontinuing all oral opiate medication?

	Commence Fentanyl 12 72 hr patch, paracetamol 1g QDS and oramorph solution PRN for breakthrough pain
	Commence Fentanyl 25 72 hr patch, paracetamol 1g QDS and oramorph solution PRN for breakthrough pain
	Commence Fentanyl 50 72 hr patch, paracetamol 1g QDS and oramorph solution PRN for breakthrough pain
	Commence Fentanyl 75 72 hr patch, paracetamol 1g QDS and oramorph solution PRN for breakthrough pain
	Commence Fentanyl 100 72 hr patch, paracetamol 1g QDS and oramorph solution PRN for breakthrough pain

□ Question 14 of 57

A 50-year-old lady is seen in the Emergency Department with abdominal pain and vomiting. She has had generalised colicky abdominal pain, worst in the centre of her abdomen, for the last 2 days. She started vomiting six hours ago and has been unable to keep fluids down. She has not opened her bowels for 3 days and her abdomen has become distended. She does not recall passing flatus today.

She is known to have ovarian cancer with metastases to her bones, liver and peritoneum. She has had a previous abdominal hysterectomy and bilateral salpingoophorectomy and two previous courses of chemotherapy. She has no other past medical history.

On examination she has a diffusely tender tympanic abdomen with no rebound or guarding. She has palpable peritoneal nodules, a 2 cm liver edge and mild shifting dullness. Bowel sounds are hyperactive. She has reduced air entry at both lung bases and mild ankle oedema.

An abdominal x-ray demonstrates dilated loops of small bowel and evidence of ascites. A CT scan of the abdomen with contrast shows small bowel obstruction with an ileal transition point adjacent to a site of peritoneal metastasis. Her liver lesions appear stable and there is no evidence of ureteric obstruction.

An NG tube is inserted and she is started on intravenous fluids and analgesia.

Which is the best initial measure to help resolve the obstruction?

	Bowel rest alone
	Dexamethasone
	Chemotherapy
	Metoclopramide
	Surgery

Overall score: **0%**

Question 16 of 57

□ □

A 68-year-old lady attends for review in the oncology clinic. She has advanced oestrogen receptor positive, HER2 negative breast cancer, with metastasis to her ribs, thoracic vertebrae and right humerus. She previously underwent right mastectomy and first line chemotherapy but has declined further chemotherapy.

She has had back and rib pain which was improved by external beam radiotherapy. She was started on alendronate to help prevent pathological fractures but has since suffered nausea, severe acid reflux and epigastric discomfort not helped by a proton pump inhibitor. Her alendronate was stopped and risedronate was trialled but resulted in similar effects and so was also discontinued.

What is the most appropriate medication to prescribe this lady to help prevent skeletal related events?

	Denosumab
	Lapatinib
	Letrozole
	Strontium
	Trastuzumab

□ Question 17 of 57

A 24-year-old man was referred to clinic with an enlarged testicle. The patient reports that he was examining himself in the shower last week and noticed that his left testicle was markedly larger than the right. He has no specific symptoms, but does describe 4kg weight loss in the last 4 months, which he had previously attributed this to a new diet. Furthermore, he has also suffered with general fatigue over the last month.

He has no past medical history and takes no regular medication. In terms of social history, he is sexually active with his partner, with whom he has been in a relationship for 3 years now. He does not drink alcohol and smoke, and denies any recreational drug use.

There are no other symptoms of note on systems enquiry.

Other than an enlarged, non-tender, left testicle, clinical examination did not reveal any abnormality. Specifically, there was no palpable lymphadenopathy and no gynaecomastia.

What is the most appropriate next step in evaluating this patient?

<input type="checkbox"/>	Ultrasound testes
<input type="checkbox"/>	Lactate dehydrogenase

□ Question 18 of 57

A 57 year old female presents after noticing a lump in her neck. She reports it being non-tender and she is only concerned about it for cosmetic purposes. She reports no other symptoms. Her past medical history includes hypertension and constipation. Her current medications include ramipril, irbesartan, amlodipine and furosemide. No family history is unavailable. On examination, her neck lump is hard, non-tender and measures 2cm by 1 cm, moves with swallowing but not with tongue protrusion. Her heart rate is 84 beats/min and blood pressure 213/130 mmHg. Examination of her joints was unremarkable with no excessive laxity.

Her blood tests are as follows:

Hb	11.2 g/dl
Platelets	$349 \times 10^9/l$
WBC	$7.2 \times 10^9/l$
Na ⁺	138mmol/l
K ⁺	4.2 mmol/l
Urea	6.9 mmol/l
Creatinine	72 μ mol/l
Adjusted calcium	3.1 mmol/l
Phosphate	0.40 mmol/l

She undergoes an outpatient ultrasound and fine needle aspiration of her neck lump. After her procedure, the recovery nurses were concerned regarding her persistent hypertension and the patient is admitted for further investigation. She develops a mild headache with no visual disturbances, resolving on its own after her blood pressure falls to 182/101 mmHg two hours later. Urinary metanephrine collection was positive.

Which investigation is likely to produce the underlying diagnosis?

	Genetic testing for RET mutation

	Genetic testing for germline VHL mutation
	Genetic testing for NF2 mutation on chromosome 22
	CT chest/abdomen/pelvis with contrast
	Urinary calcium collection

Dashboard

□ Question 18 of 57

A 57 year old female presents after noticing a lump in her neck. She reports it being non-tender and she is only concerned about it for cosmetic purposes. She reports no other symptoms. Her past medical history includes hypertension and constipation. Her current medications include ramipril, irbesartan, amlodipine and furosemide. No family history is unavailable. On examination, her neck lump is hard, non-tender and measures 2cm by 1 cm, moves with swallowing but not with tongue protrusion. Her heart rate is 84 beats/min and blood pressure 213/130 mmHg. Examination of her joints was unremarkable with no excessive laxity.

Her blood tests are as follows:

Hb	11.2 g/dl
Platelets	349 * 10 ⁹ /l
WBC	7.2 * 10 ⁹ /l
Na ⁺	138mmol/l
K ⁺	4.2 mmol/l
Urea	6.9 mmol/l
Creatinine	72 µmol/l
Adjusted calcium	3.1 mmol/l
Phosphate	0.40 mmol/l

She undergoes an outpatient ultrasound and fine needle aspiration of her neck lump. After her procedure, the recovery nurses were concerned regarding her persistent hypertension and the patient is admitted for further investigation. She develops a mild headache with no visual disturbances, resolving on its own after her blood pressure falls to 182/101 mmHg two hours later. Urinary metanephrine collection was positive.

Which investigation is likely to produce the underlying diagnosis?

	Genetic testing for RET mutation
	Genetic testing for germline VHL mutation

	Genetic testing for NF2 mutation on chromosome 22
	CT chest/abdomen/pelvis with contrast
	Urinary calcium collection

□ Question 19 of 57

A 67-year-old woman presents to the emergency department with a swollen face and shortness of breath. The swelling of her face has progressed over several weeks, but only recently has she noticed a headache, nausea and shortness of breath. She finds her symptoms bother her especially when leaning forward, but are otherwise manageable. On further questioning, she also describes feeling feverish at night and weight loss of six pounds over the last few months. She has a past medical history of COPD, depression and hypertension. She is an ex-smoker of 25 pack-years with no current alcohol intake.

On examination, she has distended veins over her neck, chest and abdomen. Her face appears swollen. A 2cm supra-clavicular is palpable on the right side. A CT scan of her chest demonstrates infra-azygous obstruction of the superior vena cava secondary to a 34mm lymph node which is reported to be suspicious of malignancy.

Observations:

Saturations	96%
Respiratory rate	18/min
Blood pressure	123/65mmHg
Heart rate	68/min
Temperature	36.8°C

What is the most appropriate immediate management plan?

	Dexamethasone
	Emergency radiotherapy
	Biopsy of the 2cm supraclavicular lymph node
	Biopsy of the 34mm intra-thoracic lymph node
	Urgent endovascular stent of the superior vena cava

Question 21 of 57

□ □

A 60-year old lady originally presented with diarrhoea and flushing 8 months ago and was diagnosed with carcinoid syndrome. She was managed medically with Octreotide and had been stable but her concerned daughter brought her today in with confusion, she seems to be seeing things and her diarrhoea was becoming a problem again. She also had an itchy rash predominantly on the back of her hands and around her neck. The GP had suggested emollients and topical corticosteroids but this had made no improvement. On examination there was an erythematous, scaly rash on the dorsum of both hands and around the neck, she had an abbreviated mental test score (AMTS) of 4/10 with no other positive findings.

What is the most likely diagnosis?

	Irritant contact dermatitis
	Brain metastases
	Dermatomyositis
	Beriberi
	Pellagra

□ Question 22 of 57

A 47-year-old woman presents to the emergency department with sudden onset of shortness of breath and pleuritic chest pain. Observations demonstrate marked hypoxia and she is given oxygen and analgesia and undergoes a chest X-ray followed by a CT pulmonary angiogram which demonstrates a pulmonary embolism. There is also an incidental finding of a nodule suspicious of metastatic disease.

She is started on treatment dose of low molecular weight heparin and admitted under the medical team for further assessment. During a more detailed history she explains that she has lost one stone in weight over two months and been feeling progressively more tired as well. She denies any other symptoms. She has a past medical history of asthma and also underwent a caesarean section three years ago. She has two children, of which she breastfed both, and has a long history of use of oral contraceptive use. She is an ex-smoker of 5 pack-years and has minimal alcohol intake. Her grandfather died of prostate cancer, and her sister developed breast cancer at the age of 52.

A complete further examination was completed and no abnormalities were found. Routine blood tests are currently pending, and a flexible bronchoscopy for biopsy of the lung nodule has been arranged. How should this patient be further investigated?

<input type="checkbox"/>	Tumour markers AFP and hCG, and mammography
<input type="checkbox"/>	CT abdomen and pelvis, tumour markers AFP and hCG, and a myeloma screen
<input type="checkbox"/>	Ultrasound abdomen and pelvis, and tumours marker AFP and hCG
<input type="checkbox"/>	CT abdomen and pelvis, and tumour markers AFP and hCG

Question 23 of 57

□ □

You are asked to review a 78 year-old male on the respiratory ward during a night shift. He is currently an inpatient being treated for an infective exacerbation of pulmonary fibrosis. You review his chest X-Ray which shows extensive left sided consolidation. His co-morbidities include end-stage renal failure (haemodialysis dependent) secondary to type 1 diabetes mellitus. He escalation plan has been discussed previously and he did not want escalation to ICU or CPR in the event of a cardiac arrest.

He has been treated with high flow oxygen and intravenous antibiotics for the past few days but nursing staff inform you he has been deteriorating in the last 24 hours. On examination he is very dyspnoeic and distressed with saturations of 72% on 80% high flow humidified oxygen.

What is the correct course of action?

	Increase the inspired oxygen concentration
	2.5mg midazolam subcutaneously
	2.5mg morphine subcutaneously
	5mg morphine orally
	100mcg alfentanil subcutaneously

Question 24 of 57

A 72-year-old Indian male presents with left loin pain and occasional frank haematuria. He reports the symptoms started 2 months ago during a visit to Mumbai but have been getting progressively worse over the past 4 days. He also reports gradual weight loss and reduced appetite as well as a non-productive cough .

His past medical history includes type 2 diabetes mellitus, hypertension and hypercholesterolaemia. On examination, his temperature is 37.8 degrees and he is haemodynamically stable.

Abdominal examination reveals a significant swelling in his left scrotum, which does not empty on lying flat. The abdomen is otherwise soft and bowel sounds are present are normal. Lastly, bilateral lower limb swelling is noted to the top of both thighs. A urine dip reveals pH 6.5 4+ blood 1+ protein 1+ leucocyte 1+ nitrite. An initial chest radiograph reveals multiple round opacities in both lung fields. Blood tests are awaited.

Which investigation is most likely to reveal the underlying diagnosis?

	CT abdomen with contrast
	Three sets of blood cultures
	Urinary protein-creatinine ratio
	Ultrasound testes
	Urine acid fast bacilli culture

	Three sets of blood cultures
	Urinary protein-creatinine ratio
	Ultrasound testes
	Urine acid fast bacilli culture

□ Question 25 of 57

A 54-year-old gentleman is reviewed 48 hours after being admitted to his local hospital with neutropaenic sepsis. He measured his temperature at home found it to be 38.2°C. Because of this, he called the chemotherapy helpline and he was advised to attend the emergency department who promptly admitted him under the care of the medical team.

He has a background of metastatic colorectal cancer and he has had chemotherapy ten days ago. He was started on piperacillin with tazobactam on admission. His temperature settled within 12 hours and investigations, including blood cultures, a chest X-ray, urine testing and a thorough examination did not find any source of infection. His initial neutrophil count was $0.4 \times 10^9/\text{l}$. Recent blood tests demonstrate a neutrophil count of $0.5 \times 10^9/\text{l}$. His vital parameters have all been normal since his temperature settled and he has not noticed any symptoms at any point.

What is the most appropriate management plan?

	Convert patient to oral antibiotics and discharge
	Keep on IV antibiotics in hospital until full course completed
	Monitor neutrophil count in hospital and discharge when greater than $1 \times 10^9/\text{l}$
	Arrange for outpatient IV antibiotics
	Change piperacillin with tazobactam to meropenem

□ Question 27 of 57

A 28 year old male is referred to endocrinology outpatient clinic for 3 months of increasing anxiety, weight loss and palpitations. His GP suspects hyperthyroidism and would appreciate your review. He has no past medical history except a fibula fracture sustained playing football aged 14 and a right orchidoplexy aged 11. On examination, he looks anxious with bilateral sweaty palms. His BMI is 13.8 kg/m² and you note a sinus tachycardia of 120 beats per minute with a systolic murmur. No neck swelling can be visualized or palpated.

His blood tests are as follows:

Hb	14.7 g/dl
Platelets	278 * 10 ⁹ /l
WBC	8.9 * 10 ⁹ /l
Na ⁺	141 mmol/l
K ⁺	3.8 mmol/l
Urea	4.5 mmol/l
Creatinine	47 µmol/l
TSH	< 0.01 mu/l
Free T4	33.3 pmol/l (normal 10-24)
Beta HCG	16000 (normal range < 5 mIU/ml for men)

What is the most appropriate next investigation?

	Ultrasound neck +/- fine needle aspiration
	Serum anti-thyroid peroxidase antibodies
	Serum free T3

	Serum FSH and LH
	Ultrasound testes

Dashboard

Overall score: **0%**

Question 30 of 57

A 63-year-old woman presents with unrelenting thoracic back pain. She finds that the pain is debilitating, especially as she helps look after her grandchildren. She has a past medical history of breast cancer diagnosed two years ago, for which she underwent a mastectomy with reconstruction. She also had postoperative radiotherapy and endocrine therapy. As she was found to be BRCA1 positive, she underwent a hysterectomy with bilateral oophorectomy as well. On examination, she is tender over the spine at T4, but neurological examination is unremarkable. What is the most appropriate imaging investigation for her back pain?

<input type="radio"/>	MRI of the whole spine within 7 days
<input type="radio"/>	MRI of the thoracic spine within 7 days
<input type="radio"/>	MRI of the whole spine within 24 hours
<input type="radio"/>	MRI of the thoracic spine within 24 hours

□ Question 31 of 57

A 37-year-old woman is referred by her GP after complaining of a swelling on the anterior aspect of her neck. On examination she is found to have a 2 cm nodule on the thyroid gland that moves on swallowing.

She has a past medical history of anxiety/depression and currently takes sertaline 100mg od. Her mother was diagnosed as having hypothyroidism in her 60's.

Thyroid functions tests are shown below:

Free T4	14 pmol/l
TSH	2.6 mu/l

A fine needle aspiration of the mass is consistent with papillary thyroid cancer. There is no current evidence of metastases. What is the most appropriate treatment?

	Total thyroidectomy followed by radioiodine-131
	Localised radiotherapy
	Total thyroidectomy
	Total thyroidectomy followed by localised radiotherapy
	Radioiodine-131

□ Question 32 of 57

A medical consult was sought regarding a 58-year-old gentleman admitted with pneumonia complaining of relentless hiccups. He was diagnosed with hepatocellular carcinoma six months ago and was deemed not for curative treatment owing to the extent of the disease. He was initially comfortable with no discernible symptoms but over the last four weeks developed hiccups. In conjunction with the palliative care nurse his GP had initially trialed domperidone and then haloperidol but with no improvement in his symptoms. He denied the presence of any other symptoms other than fatigue, and upon questioning denied the presence of abdominal pain, heartburn or early satiety.

His past medical history was comprised of alcohol dependence syndrome, chronic liver disease, hypertension and hypercholesterolaemia for which he was prescribed thiamine 100mg TDS, lactulose 10mls BD, spironolactone 100mg OD, propranolol 40mg OD, simvastatin 20mg OD as well as intravenous co-amoxiclav 625mg TDS for the treatment of his pneumonia.

Examination revealed the presence of a cachectic male. His blood pressure was 108/58 mmHg, heart rate 78 bpm, respiratory rate 18/min and temperature 36.6°C. Examination of his gastrointestinal system revealed the presence of a palpable mass in the right upper quadrant inferior to the right sterna edge and ascites with no tenderness. Examination of his neurological system revealed the absence of any focal neurological symptoms; likewise, examination of cardiovascular and respiratory systems was unremarkable.

Recent investigations revealed the following results:

Bilirubin	22 μ mol/l
ALP	221 u/l
ALT	278 u/l
Protein	62 g/l
Albumin	18 g/l

Chest x-ray: normal heart borders and lung fields

Surveillance upper GI endoscopy four months ago: normal stomach mucosal surface, no evidence of portal hypertension

Which of the following options is the best option with a view to managing his hiccups?

	Commence treatment with proton pump inhibitor
	Commence treatment with levomepromazine
	Commence treatment with dexamethasone
	Commence treatment with midazolam infusion
	Commence treatment with baclofen

□ Question 33 of 57

A 68-year-old man presents with a five-week history of lower back pain that is worse with coughing. He has noticed that he has been requiring more painkillers to the point where he is struggling to manage, especially at night. The pain is worse when straining to pass stool. He lost three kg over the last four months as well. He has a past medical history of COPD, hypertension, type two diabetes mellitus, and hypercholesterolemia. He has been admitted three times in the last year for exacerbations of COPD requiring the recurrent use of oral prednisolone. His regular medications include Symbicort, tiotropium, atorvastatin, metformin, paracetamol, codeine and Movicol. He is an ex-smoker with a 50 pack-year history and recently opted for early retirement from his job as an accountant as he was struggling with tiredness. On examination, he appears tired and his clothes appear loose fitting. Examination of his chest is unremarkable, but there is a 1cm swelling above his left clavicle. His abdomen is soft, there is no tenderness over his spine, and a neurological examination is unremarkable.

Observations:

Saturations	95%
Respiratory rate	15/min
Blood pressure	148/87mmHg
Heart rate	74/min
Temperature	37.4°C

Blood tests:

Hb	128 g/l
MCV	72 fl
Platelets	$327 \times 10^9/l$
WBC	$12.4 \times 10^9/l$
Na ⁺	136 mmol/l
K ⁺	4.2 mmol/l
Urea	4.1 mmol/l

Creatinine	77 µmol/l
------------	-----------

What is the most likely diagnosis that explains his symptoms?

	Osteoporotic vertebral collapse
	Spinal cord metastasis
	Myeloma
	Degenerative changes
	Discitis

□ Question 34 of 57

A 45-year-old man undergoing chemotherapy mentions to the nurses that he has been feeling unwell for the last two days. He has currently having treatment for metastatic lung cancer. The nurses find that his temperature is 38.2°C. His other observations are stable. He has been having chemotherapy via a peripherally inserted central catheter (PICC). On examination his line site appears normal, his chest is clear and his abdomen is soft and non-tender. What is the most appropriate next step in his management plan?

	Send a full blood count to test neutrophil levels
	Remove the PICC line and then observe if temperature settles
	Remove the PICC line then discharge with IV antibiotics
	Take blood cultures from the PICC line and peripherally then treat with IV antibiotics
	Discharge with oral antibiotics

Question 35 of 57

□ □

A 47 year old man attended his GP after checking his blood pressure at the local pharmacy. When he had it checked it was 179/102 mmHg. The GP confirmed it was high in the surgery at 186/103 mmHg. He started him on ramipril 2.5mg and titrated up the dose to 10mg over the next few weeks. His repeat measurements showed consistently high readings so the GP added amlodipine, which had very little effect despite being tolerated at the maximum dose. After failing to get adequate response with addition of a third agent the GP referred the patient to the endocrine clinic.

Observations showed a blood pressure of 190/105 mmHg and a heart rate of 98 beats per minute. On examination the man was thin with a BMI of 23 kg/m². His apex was diffuse and displaced with normal heart sounds. Chest was clear and abdomen was soft and non tender with no evidence of masses or renal bruits. He was noted to have a hard, painless nodule over the thyroid gland.

24 hour urinary catecholamines were raised and further investigations confirmed phaeochromocytoma. He was treated medically with an alpha blocker then beta blocker whilst awaiting surgery. In this period he had further investigation into the thyroid nodule, which was a cold nodule on radionucleotide scanning.

Which type of thyroid cancer would you expect this to be histologically?

	Papillary
	Follicular
	Anaplastic
	Lymphoma
	Medullary

Question 37 of 57

A 25 year old male with no significant past medical history presents with a 4 month history of palpitations. Upon further questioning he also notes an unintentional 7 kg weight loss and some heat intolerance over the same time frame.

Clinical examination reveals mild thyromegaly, fine tremor, brisk reflexes, and bilateral lid lag. He does not have any exophthalmos and the rest of the examination is unremarkable. He denies any family history of thyroid disease. He has thyroid function tests which reveal a low Thyroid-stimulating Hormone (TSH), elevated Free thyroxine (FT4) and Free Triiodothyronin (FT3), and negative anti-TPO antibodies. Thyroid uptake scan demonstrates diffusely increased uptake.

At a follow-up visit to discuss the above results he reports that he may have discovered a mass on his testicle. Your exam confirms this finding. At this point, in addition to basic labs and imaging to further evaluate this testicular mass, what laboratory test would be necessary to further evaluate the etiology behind his hyperthyroidism?

	TSH
	Human chorionic gonatropin (hCG)
	Thyroid Stimulating Antibodies
	Lactate Dehydrogenase (LDH)
	Alpha Feto Protein (AFP)

□ Question 38 of 57

A 67-year-old gentleman was admitted to the medical emergency unit with increasing drowsiness. He had been diagnosed with terminal small cell cancer of the lung which had extensively metastasised to his liver, thoracic vertebrae and femur bones. His past medical history was comprised of haemodialysis dependent polycystic kidney disease for which he attends haemodialysis three times a week as well as ischaemic heart disease, hypertension, hypercholesterolaemia and COPD. His main complaint was of progressively worsening pain in his spine and legs. This was particularly bothersome at night; a trial of bisphosphonate therapy and radiotherapy did not provide any symptomatic relief. He was initially commenced on oral morphine sulphate solution which was converted to morphine sulphate tablets (MST); he had been on 80mg BD but this was titrated by the palliative care community nurse to 100mg BD a couple of days prior to admission with excellent analgesic effect. His other prescribed medications included paracetamol 1g QDS, codeine 60mg QDS, aspirin 75mg OD, ramipril 10mg OD, bisoprolol 2.5mg OD, atorvastatin 20mg ON, Seretide 2 puffs BD & salbutamol PRN.

Examination revealed a drowsy gentleman with a GCS of 12 (E 3 M5 V4). His blood pressure was 102/68, heart rate 58bpm, respiratory rate 8/min, oxygen saturations of 95% on air and temperature 36.6°C. Other than bradypnoea, examination of his cardiovascular and respiratory systems was unremarkable. Examination of his central nervous system revealed the presence of pinpoint pupils; he was not compliant with formal neurological examination but no other focal neurological signs were found.

After appropriate inpatient care, his GCS rose to 15, with no further evidence of respiratory distress, and his subsequent dose of morphine sulphate was omitted. He, however, continued to complain of pain in his spine and legs.

What is the single best option with a view to managing his pain?

	Reduce dose of MST at 80mg BD
	Stop MST; convert to fentanyl
	Stop MST; convert to methadone
	Stop MST; convert to oxycodone
	Stop MST; convert to hydromorphone

Overall score: **0%**

□ Question 39 of 57

You are looking after a 35-year-old man who is in the oncology day unit receiving his second round of chemotherapy for a low grade non-Hodgkin's lymphoma. His lymphoma is confined to two lymph node groups in his anterior cervical chain and right inguinal region. In total there are 6 nodes with the largest being 4cm in size. He had no issues during his first round of chemotherapy apart from some nausea a week afterwards. He has no other medical problems and is on no other medications. His bloods pre-chemotherapy are as shown below:

Na ⁺	137 mmol/l
K ⁺	3.8 mmol/l
Urea	2.8 mmol/l
Creatinine	55 µmol/l
Corrected Calcium	2.39 µmol/l
Phosphate	1.05 µmol/l

What regimen would be most appropriate for prevention of tumour lysis syndrome in his case?

	Allopurinol (200mg BD)
	Fluids and allopurinol (200mg BD)
	Fluids and rasburicase (0.2mg/kg)
	Reduced dose chemotherapy
	Fluids, allopurinol (200mg BD) and rasburicase (0.2mg/kg)

Question 41 of 57

A 76-year-old woman with metastatic transitional cell carcinoma of the bladder is admitted to hospice with a 3-day history of hallucinations, confusion and pruritus. Her only other symptoms are intermittent vomiting and pelvic discomfort. She has a past medical history of hypertension and has recently completed a course of radiotherapy for bone metastases. She takes paracetamol, morphine sulphate, cyclizine, dexamethasone and a herbal flower remedy for anxiety.

On examination, she is cachectic and frail. The lungs are clear and heart sounds are normal. Pulse rate is 85 beats per minute and blood pressure 130/80mmHg. She is afebrile.

Neurological examination reveals myoclonus. She is mildly hypotonic and all reflexes are diminished. There is miosis on cranial nerve examination.

Blood tests show:

Hb	12.1 g/dl
Platelets	250 * 10 ⁹ /l
WBC	12 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	4.3 mmol/l
Urea	5 mmol/l
Creatinine	80 µmol/l
Calcium (unadjusted)	2.1 mmol/l

Bilirubin	15 µmol/l
ALP	45 u/l
ALT	15 u/l

AST	20 u/l
Albumin	28 g/l

Urine dip: no abnormality

What is the most likely diagnosis?

	Hypercalcaemia
	Opioid toxicity
	Sepsis
	Corticosteroid psychosis
	Brain metastases

A 76-year-old woman with metastatic transitional cell carcinoma of the bladder is admitted to hospice with a 3-day history of hallucinations, confusion and pruritus. Her only other symptoms are intermittent vomiting and pelvic discomfort. She has a past medical history of hypertension and has recently completed a course of radiotherapy for bone metastases. She takes paracetamol, morphine sulphate, cyclizine, dexamethasone and a herbal flower remedy for anxiety.

On examination, she is cachectic and frail. The lungs are clear and heart sounds are normal. Pulse rate is 85 beats per minute and blood pressure 130/80mmHg. She is afebrile.

Neurological examination reveals myoclonus. She is mildly hypotonic and all reflexes are diminished. There is miosis on cranial nerve examination.

Blood tests show:

Hb	12.1 g/dl
Platelets	250 * 10 ⁹ /l
WBC	12 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	4.3 mmol/l
Urea	5 mmol/l
Creatinine	80 µmol/l
Calcium (unadjusted)	2.1 mmol/l

Bilirubin	15 µmol/l
ALP	45 u/l
ALT	15 u/l

AST	20 u/l
Albumin	28 g/l

Urine dip: no abnormality

What is the most likely diagnosis?

	Hypercalcaemia
	Opioid toxicity
	Sepsis
	Corticosteroid psychosis
	Brain metastases

□ Question 42 of 57

A 69-year-old male patient presents with worsening mouth soreness and painful swallowing, progressively getting worse over the last week. He started radical radiotherapy for a base of mouth squamous cell cancer three weeks ago. He also has a PEG in situ. He was recently seen by the dietician and is now having fluid and Ensure nutritional supplements via his PEG. He had been given soluble paracetamol by the specialist nurse, but this has failed to control his pain.

On examination, his oral cavity appears inflamed with multiple small ulcers posterior to his lower lip. There are no patches or plaques inside. You change the paracetamol to liquid co-codamol and give him a topical lidocaine gel at 2% strength. What is the most appropriate next step in management to control his symptoms?

	Benzydamine mouthwash
	Menthol mouthwash
	Chlorhexidine mouthwash
	Fluconazole
	Metronidazole

A 51-year-old woman is reviewed in clinic. Two months ago she underwent an operation to remove a medullary thyroid cancer after presenting with diarrhoea and a neck lump. Genetic testing showed she has a mutation of the RET oncogene. The patient reports being well and there are no signs of local recurrence on examination.

What is the most appropriate test to monitor for recurrence?

	Thyroglobulin
	Thyroid transcription factor-1
	Chromogranin
	Calcitonin
	S100 protein

□ Question 44 of 57

A 62-year-old man with metastatic small cell lung cancer is admitted with a shortness of breath, cough and purulent sputum.

His chest x-ray shows a right lower lobe pneumonia with partial collapse of the right lung. He has a bulky primary tumour at the right hilum and extensive hilar lymphadenopathy.

He is treated with IV antibiotics, fluids and oxygen. His symptoms improve over the next 5 days and his breathing is comfortable on 2 litres of oxygen via nasal cannulae. His pain is controlled on 20mg long-acting morphine sulphate twice daily. The decision is made to discharge him to a hospice for end-of-life care. However, due to the proximity of his lung tumour to major vessels, he is at risk of a major terminal bleed.

Which medication should the hospice be advised to give in the event of a major bleed?

	Haloperidol
	Midazolam
	Morphine
	Tranexamic acid
	Vitamin K

□ Question 45 of 57

□ □

A 65-year-old man is referred to the oncology team after presenting to the emergency department. The patient described a three-week history of progressive thoracic back pain. The pain was localised to a point between the patient's shoulder blades, and was exacerbated by movement and coughing.

In addition, over the previous 6 hours, the patient reported that he had been struggling to stand up unassisted, and was having difficulty walking. The sudden change in his mobility had been the event that had prompted his attendance at hospital. When questioned directly, the patient described intermittent tingling sensations in his lower legs, but denied any loss of sensation. There had been no dysfunction of his bladder or bowels.

The patient had been diagnosed with prostate cancer five years previously. This had been treated with a radical prostatectomy and hormone therapy. The patient had moved area two years previously, and had subsequently been lost to urological follow-up. Despite his previous cancer treatment, the patient stated that he was very fit and active, playing golf three times a week and taking an active role in the care of his grandchildren.

Peripheral nerve examination of lower limbs: tone generally increased bilaterally; power generally slightly reduced (4+/5) bilaterally; normal coordination; no impairment of light touch or sharp touch sensation; knee and ankle jerks brisk bilaterally, plantar responses up going bilaterally.

Digital rectal examination: preserved peri-anal sensation and normal tone.

Bed-side bladder scan: 50 ml

MRI whole spine: metastatic invasion and collapse of T10 vertebral with spinal cord compression.

The patient was treated with analgesia and dexamethasone while definitive treatment was planned.

What is most appropriate first-line treatment of patient's spinal cord compression?

	Surgical tumour resection and spinal cord stabilisation with adjuvant radiotherapy
	Radiotherapy: single dose 8 Gy
	Chemotherapy: docetaxel

	Best supportive care
	Chemotherapy: cabazitaxel

Dashboard

□ Question 46 of 57

A 72-year-old gentleman presents with a peeling and erythematous rash on both of his hands. He has noticed slight tingling in the same area but denies pain. He has a past medical history of colorectal cancer which was managed surgically with an anterior resection. He developed local recurrence of his cancer five months post-operatively. He is now on palliative chemotherapy with capecitabine and oxaliplatin every two weeks in order to control progression. His last treatment was one week ago. He has a history of type two diabetes mellitus, depression and has had a cholecystectomy when he was younger. On examination he appears frail and cachectic, but systemically well. His hands are shown to have patchy palmar erythema with mild desquamation. A similar rash is present on the soles of his feet.

Observations:

Saturations	97%
Respiratory rate	17/min
Blood pressure	132/73mmHg
Heart rate	71/min
Temperature	37.3°C

What is the most likely diagnosis?

	Erythromelalgia
	Palmoplantar psoriasis
	Palmar-plantar erythrodysesthesia
	Paraneoplastic syndrome
	Cellulitis

Overall score: **0%**

□ Question 47 of 57

A 40-year-old man is seen in the Emergency Department with breathlessness.

He was diagnosed with non-Hodgkin lymphoma 6 months ago and has been receiving chemotherapy. He is awaiting an appointment in haematology outpatients to assess his response to chemotherapy.

He describes becoming more breathless over the last week and feeling that his arms and face are puffy. He has had no chest pain, cough or fevers.

On examination his oxygen saturations are 92% on air and his heart rate is 112 beats per minute. His chest is clear and he is unable to lay flat for his abdomen to be examined due to his breathlessness. His face appears flushed and he has oedema of the arms and hands. His neck veins appear engorged.

Chest x-ray shows a widened mediastinum with extensive lymphadenopathy.

A CT scan of the thorax confirms superior vena cava obstruction (SVCO). The scan is reviewed by the haematology team who explain to him that his lymphoma has progressed despite chemotherapy.

He is started on steroids and a proton pump inhibitor.

What is the next step in the management of this gentleman's SVCO?

	Chemotherapy
	Observation
	Radiotherapy
	Stent insertion
	Surgery

□ Question 50 of 57

A 50-year-old man is diagnosed with high-grade non-Hodgkin's lymphoma and starts his regimen of R-CHOP chemotherapy. Two days after his chemotherapy he complains of feeling increasingly weak, lethargic and generally unwell. He has developed persistent vomiting and is unable to tolerate oral fluids.

He has a history of recurrent gout but has been unable to tolerate allopurinol.

On examination, he looks unwell and pale. He seemed short of breath with a respiratory rate of 28 per minute. His temperature is 36.5°C, heart rate 110 bpm, blood pressure 100/60 mmHg.

His heart sounds were normal. His JVP was raised by 4cm lying at 45 degrees in the bed. Examination of the chest revealed fine bibasal inspiratory crepitations. Pitting oedema was present to mid-shins bilaterally.

Abdominal examination was unremarkable.

On neurological examination, there was normal tone and sensation to all limbs. General weakness was noted.

The house officer has taken bloods:

Na+	137 mmol/L
K+	6.2 mmol/L
Urea	15 mmol/L (previously 8)
Creatinine	240 µmol/L (previously 100)
Hb	100 g/L
WBC	$10.0 \times 10^9/L$
Corrected Calcium	1.95 mmol/L
Phosphate	2.3 mmol/L
Uric acid	640 mmol/L
LFTs	Normal

Chest x-ray shows congested lung fields.

ECG demonstrates tall T waves.

In view of the diagnosis which of the following is most likely to treat the hyperuricaemia?

	IV calcium gluconate, insulin and dextrose infusion
	Allopurinol
	Rasburicase
	IV fluids
	IV electrolyte replacement

Dashboard

□ Question 52 of 57

A 68-year-old gentleman was admitted to the medical admissions unit with increasing drowsiness. He had been diagnosed with primary small cell carcinoma of the lung six months ago and had declined curative chemotherapy. At the time of diagnosis there was no evidence of metastasis, and his past medical history comprised of chronic obstructive pulmonary disease, ischaemic heart disease, hypertension, hypercholesterolaemia and depression.

His wife had taken him to the Emergency Department having noted that he had been increasingly drowsy over the last few hours, as well as developing new onset confusion. He had otherwise been relatively well prior to the admission. He had consulted his GP about new onset generalised aches and pains within the last four weeks for which his GP had commenced Oramorph solution PRN. Since then he had developed abdominal pain which the GP had diagnosed as secondary to opiate-induced constipation and he was accordingly prescribed lactulose 15ml BD with partial relief of his symptoms. There had been no evidence of weakness or numbness and no evidence of speech impairment; as far as his wife was aware he had taken the prescribed dose of oramorph. His drug history comprised of oramorph solution 10mg BD, paracetamol 1g QDS, dihydrocodeine 60mg QDS, lactulose 15ml BD, aspirin 75mg OD, atorvastatin 20mg ON, bisoprolol 2.5mg OD, Ramipril 2.5mg OD and furosemide 40mg OD.

Examination revealed a drowsy gentleman with a GCS of 12 (E 3 M5 V4). His blood pressure was 102/68, heart rate 58bpm, respiratory rate 10/min, oxygen saturations of 95% on air and temperature 36.6°C. Examination of his cardiovascular and respiratory systems were unremarkable. Examination of his central nervous system revealed the presence of normal sized pupils; he was not compliant with formal neurological examination but no other focal neurological signs were found. There was no evidence of neck stiffness and Kernig's sign was negative. He was not cooperative with an abbreviated mental state examination.

Which investigation is most likely to be diagnostic of the underlying cause?

	Urgent CT head scan
	Urgent serum liver function and calcium profile
	Urgent isotope bone scan
	Urgent septic screen
	Urgent PET scan

She describes a tingling sensation that started three days previously, which then progressed to swelling and redness of both her hands. She now finds that is impacting on what she able to do at home. Over the last day, she has noticed a blister as well. She has otherwise been suffering from fatigue and nausea since starting chemotherapy. She has a past medical history of left breast cancer managed with wide local excision and axillary node clearance following adjuvant radiotherapy and chemotherapy with docetaxel, as well as endocrine therapy. What is the most appropriate management?

	Topical hydrocortisone
	Prednisolone
	Flucloxacillin
	Stop endocrine treatment
	Dose reduction of docetaxel

Question 55 of 57

□ □

A 72-year-old woman presents to the emergency department with a painful and swollen leg. This has developed over two days, and she otherwise feels well in herself. She was recently away on holiday to Spain and returned four weeks ago. She is able to mobilise independently and has had no reduced periods of mobility. She has a background breast cancer diagnosed four years ago, which unfortunately relapsed and spread into her liver. She is now on hormonal treatment only.

On examination, her left leg is swollen and red, and the calf diameter is significantly larger on the left side. A doppler ultrasound scan demonstrates a left-sided deep vein thrombus. What is the most appropriate anticoagulation strategy?

	Three months of low molecular weight heparin
	Six months of low molecular weight heparin
	Six months of a new oral anticoagulant (NOAC)
	Three months of warfarin
	Six months of warfarin

□ Question 56 of 57

A 69-year-old gentleman presented for routine follow-up in the oncology clinic. He has metastatic poorly differentiated adenocarcinoma of unknown primary. He commenced palliative chemotherapy with oxaliplatin and fluorouracil two months ago. The most recent CT scan demonstrated stable disease.

Ten days ago he was admitted to the local emergency department with fever and diagnosed with neutropenic sepsis, of which the cause was not clear. He was admitted for IV Tazocin for five days then discharged with co-amoxiclav and filgrastim (G-CSF). He currently feels well. On examination there are no abnormalities.

Observations:

Saturations	95%
Respiratory rate	14/min
Blood pressure	152/83mmHg
Heart rate	69/min
Temperature	37.3°C

Blood tests:

Date	24/10/2016	10/10/2016
Hb	124g/l	135g/l
Platelets	285* 10 ⁹ /l	322* 10 ⁹ /l
WBC	23.6* 10 ⁹ /l	0.2* 10 ⁹ /l

What is the most appropriate course of action?

	Restart oral co-amoxiclav
	Arrange admission for IV tazocin
	Arrange admission for IV meropenem

	Start prednisolone
	Stop filgrastim (G-CSF)

□ Question 57 of 57

A 16 year old male is referred to your clinic after reporting feeling increasingly tired at school over the past 2 months. His parents are similarly concerned that their son seems to be relying on large volumes of lucozade to keep himself alert during this stressful period of secondary school examinations. He reports no headaches. The patient was born following a normal pregnancy and development until he was 12 years old, when he underwent chemotherapy and radiotherapy treatment for an optic chiasm glioma, forcing him to miss one academic year of school. On completion of his treatment, he returned to school and has been achieving good grades. There is no other past medical or family history.

On examination, the patient is short for his age (at 2nd centile) and you note an absence of facial hair or other secondary sexual characteristics. He is thin with a BMI of 13.7 kg/m². Chest, cardiovascular and abdominal examinations are unremarkable. There are no skin lesions. Neurological examination including cranial nerve is unremarkable. His initial blood tests are as follows:

Hb	14.2 g/dl
MCV	89 fl
Platelets	410 * 10 ⁹ /l
WBC	7.4 * 10 ⁹ /l
Na ⁺	139 mmol/l
K ⁺	4.6 mmol/l
Urea	5.1 mmol/l
Creatinine	44µmol/l
FSH	low
ACTH	low
TSH	0.13 mu/l

What is the likely diagnosis?

--	--

	Cranial radiation injury
	Glioma recurrence in optic chiasm
	Klinefelter's syndrome
	Turner's syndrome
	Haemochromatosis

Dashboard

□ Question 1 of 144

□ □

A 53-year-old patient with previous hyperparathyroidism and recurrent urinary tract infections presents with an episode of haematuria and aching right loin pain radiating to her groin.

On examination there is some mild right flank pain, but no palpable masses or organomegaly. Urine dip shows blood 3+, protein 1+ and leucocytes 2+.

A CT scan of the abdomen demonstrates a staghorn calculus.

Together with increased urinary ammonia, what condition is required for the formation of struvite stones?

	Diet rich in dairy products
	Bacteria that do not generate urease
	Urinary pH >7.2
	Hypocalcaemia
	Female sex

□ Question 2 of 144

A 28-year-old man with a family history of autosomal dominant polycystic kidney disease attended renal clinic for assessment. The patient's mother and his two older siblings have all previously been diagnosed with the disease. The patient admitted that he had been reluctant previously to be assessed for ADPKD while he had been asymptomatic but that he was now keen to undergo investigation and treatment. The patient denied any previous medical history and did not take any regular medications.

Clinical examination of the abdomen was unremarkable with a euvoelaemic fluid status. Blood pressure measured in the clinic was 132 / 82 mmHg.

Please see below for results of investigations arranged following clinic assessment.

Urea	6.7 mmol / L
Creatinine	85 micromol / L
Estimated globular filtration rate	> 90 mL / min / 1.73 m ²
Sodium	140 mmol / L
Potassium	3.9 mmol / L

Renal tract ultrasound: left kidney 10 cm in length with 3 cysts; right kidney 9.7 cm in length with 2 cysts; no renal or ureteric calculi; no hydronephrosis or hydroureter.

Urine dipstick: proteinuria ++; otherwise unremarkable

What is the appropriate therapeutic management of the patient at the present time?

	Ramipril with blood pressure target < 140 / 90 mmHg
	Hydralazine with blood pressure target < 120 / 70 mmHg
	Ramipril with blood pressure target < 110 / 75 mmHg

	Tolvaptan
	Hydralazine with blood pressure target < 130 / 80 mmHg

□ Question 3 of 144

A 53-year-old male presents acutely as a primary percutaneous coronary intervention (PPCI) call after sudden onset chest pain of onset 3 hours ago, associated with nausea, vomiting and profuse sweating. His ECG in the ambulance demonstrates ST elevation noted on V2 V5. His past medical history includes include hypertension, type 2 diabetes mellitus, chronic kidney disease (creatinine baseline = 170 $\mu\text{mol/l}$ at the renal clinic 2 months ago). He is taken straight to the cardiac catheter laboratory, where he undergoes angioplasty and a single drug eluting stent to his left anterior descending artery. On examination, he is pain-free, warm peripherally without respiratory distress. Capillary refill time is less than 2s and jugular venous pulse at 3 cm above the angle of Louis. His heart sounds and chest are unremarkable. A post-procedure transthoracic echocardiogram demonstrates moderate left ventricular impairment with no valve abnormalities.

At 24 hours after admission, his blood tests are repeated and are as follows:

WCC	92 g/l
Hb	13.5 * $10^9/\text{l}$
Plt	198* $10^9/\text{l}$
Na	138 mmol/l
K	4.2 mmol/l
Urea	12.9 mmol/l
Creat	254 mmol/l
Trop	0.87 (normal < 0.03)

What is the most appropriate next management step in addition to optimisation of hydration status?

	Monitor with daily U+Es
	Haemofiltration
	Organise urgent outpatient haemodialysis

	Intravenous n-acetylcysteine
	Intravenous mannitol

Dashboard

□ Question 4 of 144

You are the medical doctor in an acute medical clinic. A 32-year old gentleman who is an intravenous drug user of heroin has been referred by his GP for renal impairment. He feels well in himself and denies any urinary symptoms. His observations are: temperature 36.8°C, pulse 98/min, blood pressure 148/68 mmHg, respiratory rate 14/min, sats 95% on room air.

His urine dipstick has 3+ proteinuria, nil else. Recent hepatitis and HIV tests were -ve. His blood tests are as below:

Na ⁺	138 mmol/l
K ⁺	4.6 mmol/l
Bicarbonate	22 mmol/l
Urea	9.8 mmol/l
Creatinine	152 µmol/l
eGFR	58 ml/min (baseline 80)

What is the most likely cause for his renal impairment?

	Septic emboli
	Renal vein thrombosis
	Focal segmental glomerulosclerosis
	Membranous nephropathy
	Membranoproliferative glomerulonephritis

Overall score: **0%**

Question 5 of 144

□ □

An 82-year-old female presents to clinic with her daughter complaining of a four month history of urinary incontinence. She explains that she has not previously had problems with continence. Her only past medical history include hypertension and angina. Now, she is incontinent of urine only when she laughs or coughs. At times, she reports sudden urges to urinate at all times during the day, resulting in a leak when she is unable to reach the toilet in time. This is significantly impacted on her sleep as well as it is increasingly frequent at night. The patient has reduced her caffeine intake already and has commenced 'bladder training' recommended by her GP. What additional management would you commence?

	Pelvic floor exercises only
	Pelvic floor exercises and tolterodine
	Pelvic floor exercises and duloxetine
	Pelvic floor exercises and desmopressin
	Long term urinary catheter

Dashboard

Overall score: 0%

□ Question 6 of 144

A 45 year old woman attends her General Practitioner to report a three month history polyuria. Having previously not been troubled by urinary symptoms, the patient now needs to pass urine up to every 60 to 90 minutes during the day and is being woken from sleep on at least two occasions per night. There is no history of increased urinary urgency or dysuria. The patient had not changed her fluid intake in recent weeks and consumes minimal caffeine and alcohol. Otherwise the patient had been fairly well in herself although had noticed a tendency to loose stools and 4 Kg weight loss over recent weeks.

The patient was normally fit and well and worked as an accountant. Past medical history included only an appendicectomy as a child and there were no previous pregnancies. The patient reported that her twin sister had been diagnosed with coeliac disease 5 years previously. There were no regular medications or allergies.

On examination the patient was slim and appeared slightly anxious. Cardiovascular, respiratory and ocular examination was normal. There were no skin rashes.

Initial investigations requested by the General Practitioner are listed below.

Haemoglobin	12.4 g / dL
White cell count	$6.5 \times 10^9/l$
Platelets	$329 \times 10^9/l$
Urea	3.5 mmol / L
Creatinine	75 micromol / L
Sodium	142 mmol / L
Potassium	3.7 mmol / L
Calcium (adjusted)	2.4 mmol / L
Haemoglobin A1C	5.3 % (reference 4-6)
Serum glucose (random)	4.7 mmol / L

Urine dipstick: negative for nitrites; negative for leucocytes; negative for glucose; negative for ketones; negative for

protein; negative beta-HCG

Urine microscopy, culture and sensitivities: white cell count < 10 / mm³; no growth

What is most appropriate next test to diagnose cause of polyuria?

	Paired serum and urine osmolality
	Paired serum and urine osmolality after desmopressin
	Urodynamic studies
	Thyroid function tests
	Serum tissue transglutaminase IgA

□ Question 7 of 144

A 52-year-old female with a history of systemic lupus erythematosus presents to the emergency department with 4 days history of high-grade fever and productive cough. She recently travelled to France with her husband and has been feeling unwell ever since she got back home.

Her medication history included prednisolone 10mg daily, and hydroxychloroquine 200mg twice daily which she has been taking for the last 12 years. She is additionally on once-yearly zoledronic acid and occasional naproxen.

On examination, she has a temperature of 38.5°C and a pulse of 130 bpm which is regular and low volume. Her blood pressure is 80/50 mmHg and she has cold peripheries. She has a confluent rash on her cheeks with nasolabial sparing. Examination of her respiratory system reveals a patch of bronchial breathing in the left middle of the chest. The remaining physical examination is essentially unremarkable.

Laboratory investigations reveal:

Hb	110 g/dl
MCV	85 fl
MCH	24 pg (27 - 32 pg)
WBC	$17 \times 10^9/l$
Plt	$450 \times 10^9/l$
Urea	14.9 mmol/l
Creatinine	298 μ mol/l
Na ⁺	128 mmol/l
K ⁺	3.9 mmol/l
Albumin	32g/l

Urine dipstick shows protein 1+

Urinary electrolytes reveal:

Urinary specific gravity	1.031 (1.010 - 1.020)
Urinary osmolality (mOsm/kg)	675 (350 - 500)
Urinary sodium (mmol)	8 (20 - 40)
Fe _{Na}	0.2% (1%)

Which of the following is the most appropriate initial management option?

	IV hydration with 0.9% saline
	Increase prednisolone to 1mg/kg/day
	Start mycophenolate mofetil
	IV hydration with 3% saline
	Commence inotropic support with dobutamine

□ Question 7 of 144

A 52-year-old female with a history of systemic lupus erythematosus presents to the emergency department with 4 days history of high-grade fever and productive cough. She recently travelled to France with her husband and has been feeling unwell ever since she got back home.

Her medication history included prednisolone 10mg daily, and hydroxychloroquine 200mg twice daily which she has been taking for the last 12 years. She is additionally on once-yearly zoledronic acid and occasional naproxen.

On examination, she has a temperature of 38.5°C and a pulse of 130 bpm which is regular and low volume. Her blood pressure is 80/50 mmHg and she has cold peripheries. She has a confluent rash on her cheeks with nasolabial sparing. Examination of her respiratory system reveals a patch of bronchial breathing in the left middle of the chest. The remaining physical examination is essentially unremarkable.

Laboratory investigations reveal:

Hb	110 g/dl
MCV	85 fl
MCH	24 pg (27 - 32 pg)
WBC	$17 \times 10^9/l$
Plt	$450 \times 10^9/l$
Urea	14.9 mmol/l
Creatinine	298 μ mol/l
Na ⁺	128 mmol/l
K ⁺	3.9 mmol/l
Albumin	32g/l

Urine dipstick shows protein 1+

Urinary electrolytes reveal:

Urinary specific gravity	1.031 (1.010 - 1.020)
Urinary osmolality (mOsm/kg)	675 (350 - 500)
Urinary sodium (mmol)	8 (20 - 40)
Fe _{Na}	0.2% (1%)

Which of the following is the most appropriate initial management option?

□ Question 8 of 144

A 17-year-old male presents with bilateral lower limb and periorbital swelling of gradual onset about 3 days ago. He reports no pain or tenderness elsewhere. He has no past medical, drug allergies and does not take any medications on a regular basis. He has been smoking cigarettes and marijuana for 2 years 'occasionally' but refuses to acknowledge an estimate.

About 5 weeks ago, he had a few days of a 'cough and cold', during which he developed swollen glands in his neck, a sore throat and a temperature of 37.6°C. He sought medical attention from his GP, who prescribed antibiotics to little avail. The illness spontaneously resolved after 3 days.

A urine dip reveals 4+ protein, no blood, leucocytes or nitrites. A 24-hour urine collection demonstrated protein of 3.8g.

His selected blood tests demonstrate:

Urea	6.5 mmol/l
Creatinine	90 µmol/l
Albumin	21 g/l
Complement	normal
HIV p24 antigen	negative

His renal biopsy demonstrates podocyte fusion.

What is the cause of his presentation?

	Mesangioproliferative glomerulonephropathy
	Minimal change disease
	HIV seroconversion
	Diffuse proliferative glomerulonephritis

	Secondary focal segmental glomerulosclerosis
--	--

□ Question 9 of 144

A 38-year-old known ulcerative colitis (UC) patient presents to the emergency department with excruciating sudden onset left sided loin to groin pain. The patient has no other medical problems. He had a panproctocolectomy and ileostomy 5 years ago after he suffered a colitis flare which did not respond to medical therapy. On examination he is in obvious pain and his urine dip shows 3+ RBCs. He is given diclofenac and 5mg IV morphine and his pain settles. His observations after he is pain-free are normal.

His blood tests are:

Hb	145 g/l
Platelets	455 * 10 ⁹ /l
WBC	11.9 * 10 ⁹ /l

Na ⁺	136 mmol/l
K ⁺	4.5 mmol/l
Urea	8.8 mmol/l
Creatinine	99 µmol/l
Calcium (adj)	2.48 mmol/L
CRP	<10 mg/L

He undergoes a KUB X-ray which shows a left sided stone in the ureter. What is the likely type of renal stone?

	Urate
	Magnesium pyrophosphate
	Xanthine

	Calcium oxalate
	Cystine

□ Question 10 of 144

A 55-year-old known rheumatoid arthritis patient is admitted via the emergency department with sudden onset severe right upper quadrant pain. She has vomited several times and felt hot and feverish. She has had no diarrhoea. She has been a bit tired over the last few months and recently saw her GP for swelling of her ankles. He prescribed her a short course of furosemide but this has now finished after there was no improvement. She has a past medical history of hypertension. Her regular medication is penicillamine and ramipril. On examination, she is very tender in the right upper quadrant with voluntary guarding. There is no palpable hepatosplenomegaly. She has pitting oedema to the knee. She is has a low-grade fever of 37.5. Her urine dip shows 3+ of protein and 1+ RBCs.

Her blood tests show

Hb	126 g/l
Platelets	458 * 10 ⁹ /l
WBC	9.7 * 10 ⁹ /l
Neutrophils	7.7 * 10 ⁹ /l

Na ⁺	139 mmol/l
K ⁺	4.9 mmol/l
Urea	25 mmol/l
Creatinine	300 µmol/l
CRP	12 mg/l

Bilirubin	20 µmol/l
ALP	189 u/l
ALT	110 u/l
Albumin	26 g/l

What is the most likely cause of her right upper quadrant pain?

	Biliary colic
	Acute cholecystitis
	Acute portal vein thrombosis
	Adult polycystic kidney disease
	Acute viral hepatitis

□ Question 11 of 144

A 37-year-old patient presents to the Emergency Department with worsening swelling of his legs over the past few weeks. He has never had this problem before. He does not feel short of breath and has no chest pain. His past medical history includes asthma, hepatitis C and depression.

The patient appears to have sunken cheeks and a number of depressions in his skin across his upper arms and chest. On auscultation his chest is clear, heart sounds I+II are present and there are no added sounds. His abdomen is soft and non-tender. He has pitting oedema to the knees bilaterally.

Observations are as follows: temperature 36.3°C, blood pressure 179/111 mmHg, heart rate 89/min, respiratory rate 16/min, saturations 97% on air

Initial investigations are as follows:

Hb	120 g/l
Platelets	$170 \times 10^9/l$
WBC	$9.2 \times 10^9/l$
Neuts	$4.0 \times 10^9/l$
Na ⁺	144 mmol/l
K ⁺	4.9 mmol/l
Urea	12.6 mmol/l
Creatinine	166 μ mol/l
Adjusted calcium	2.35 mmol/l
Albumin	26 g/l

Urine: blood ++, nitrites -ve, leucocytes -ve, protein +++

What is the single most likely underlying diagnosis?

	Diffuse proliferative glomerulonephritis
	Focal segmental glomerulosclerosis
	IgA nephropathy
	Mesangiocapillary glomerulonephritis
	Renal amyloid

□ Question 13 of 144

A 45-year-old woman presents with fever, rigors and left iliac fossa pain to the emergency department in Manchester. She has polycystic kidney disease (PKD) and 2 months ago she received a renal transplant on the left side for end-stage renal failure. She is currently on mycophenolate mofetil 1g twice daily and prednisolone 10 mg once daily.

Investigations:

White cell count	16 x 10 ⁶ / dL
Urine Microscopy	White cells + + +, no organisms seen.

Her kidney function tests are as follows:

	Post-Transplant	Current Admission
Urea	4.1 mmol/L	9.1 mmol/L
Creatinine	98 µmol/L	140 µmol/L
Potassium	4.9 mmol/L	5.3 mmol/L

What is the most likely diagnosis?

	Kidney abscess (infection of PKD cyst)
	Iatrogenic renal nephrolithiasis
	Opportunistic fungal infection
	Acute graft rejection
	Chronic graft rejection

Overall score: **0%**

□ Question 14 of 144

A 40 year old man attended his General Practitioner and reported ongoing frequency of urination for the past few weeks. The patient reported passing very dilute urine. There was no history of hesitancy of micturition or terminal dribbling.

The patient was also under investigation for suspected liver disease after presenting with mild jaundice 3 weeks previously. Some initial investigations had been completed but hepatology clinic review was still awaited. There was no other past medical history and the patient took no regular or illicit medications. The patient worked as an insurance agent, lived alone and drank only minimal amounts of alcohol.

A summary of initial investigations arranged by the General Practitioner and through endocrine clinic are given below.

Haemoglobin	11.5 g / dL
White cell count	$6.5 \times 10^9/\text{L}$
Neutrophils	$4.2 \times 10^9/\text{L}$
Platelets	$156 \times 10^9/\text{L}$
Urea	9.3 mmol / L
Creatinine	145 micromol / L
Sodium	156 mmol / L
Potassium	3.9 mmol / L
Albumin	30 g / L
Alkaline phosphatase	170 U / L
ALT	150 U / L
Bilirubin	80 micromol / L
Ferritin	439 ng / mL
Serum immunoglobulins	No abnormality detected
Hepatitis viruses	No abnormality detected

Thyroid stimulating hormone	1.0 microU / L (reference 0.4-5.0)
T4 free serum	13.4 pmol / L (reference 8.5-15.2)
Plasma osmolality	390 mmol / L (reference 280-295)
Urine osmolality	80 mmol / L (reference 100-900)
Plasma osmolality (after desmopressin)	267 mmol / L (reference 280-295)
Urine osmolality (after desmopressin)	265 mmol / L (reference 100-900)
Random serum glucose	4.5 mmol / L

What is the cause of the patient's polydipsia?

<input type="checkbox"/>	Nephrogenic diabetes insipidus
<input type="checkbox"/>	Liver cirrhosis secondary to haemachromatosis
<input type="checkbox"/>	Primary polydipsia
<input type="checkbox"/>	Chronic renal failure
<input type="checkbox"/>	Cranial diabetes insipidus

□ Question 15 of 144

□ □

A 71-year-old gentleman is reviewed in hospital prior to discharge after having received treatment for an exacerbation of COPD. His systolic blood pressure has been recorded as measuring between 138mmHg to 156mmHg. He has a background of ischaemic heart disease, gout, gallstones and a fractured neck of femur which was repaired with a dynamic hip screw. He is found to have ACR of 31mg/mmol. He normally takes allopurinol, aspirin, tiotropium, Symbicort, salbutamol.

What is the most appropriate pharmacological management for his hypertension?

	ACE-inhibitor
	Calcium channel blocker
	Thiazide-like diuretic
	Beta-blocker
	Alpha-blocker

□ Question 16 of 144

A 30-year-old woman with systemic lupus erythematosus is seen in the rheumatology clinic for annual follow-up. Recently she has felt well in herself and continues on hydroxychloroquine. She has not required additional steroid or analgesia for the last three years.

Her routine blood tests are as follows:

Hb	112 g/l	Na ⁺	136 mmol/l
Platelets	252 * 10 ⁹ /l	K ⁺	4.9 mmol/l
WBC	6 * 10 ⁹ /l	Urea	15 mmol/l
Neuts	4.5 * 10 ⁹ /l	Creatinine	180 µmol/l
Lymphs	1 * 10 ⁹ /l	CRP	23 mg/l

Her urine dipstick shows 3+ blood and 2+ protein.

Given that her renal function was previously normal, her rheumatologist refers her for ultrasound kidneys which shows normal sized kidneys with no hydronephrosis and normal renal artery dopplers.

Following discussion at MDT, it is recommended she undergo kidney biopsy for suspected lupus nephritis.

Which class of lupus nephritis would carry the worst prognosis?

	Focal
	Diffuse
	Minimal mesangial
	Mesangial proliferative
	Membranous

□ Question 16 of 144

A 30-year-old woman with systemic lupus erythematosus is seen in the rheumatology clinic for annual follow-up. Recently she has felt well in herself and continues on hydroxychloroquine. She has not required additional steroid or analgesia for the last three years.

Her routine blood tests are as follows:

Hb	112 g/l	Na ⁺	136 mmol/l
Platelets	252 * 10 ⁹ /l	K ⁺	4.9 mmol/l
WBC	6 * 10 ⁹ /l	Urea	15 mmol/l
Neuts	4.5 * 10 ⁹ /l	Creatinine	180 µmol/l
Lymphs	1 * 10 ⁹ /l	CRP	23 mg/l

Her urine dipstick shows 3+ blood and 2+ protein.

Given that her renal function was previously normal, her rheumatologist refers her for ultrasound kidneys which shows normal sized kidneys with no hydronephrosis and normal renal artery dopplers.

Following discussion at MDT, it is recommended she undergo kidney biopsy for suspected lupus nephritis.

Which class of lupus nephritis would carry the worst prognosis?

	Focal
	Diffuse
	Minimal mesangial
	Mesangial proliferative
	Membranous

☐ Question 17 of 144

A 60 year female with end-stage renal failure is referred to the medical assessment unit with painful legs. She has a past history of atrial fibrillation, rheumatoid arthritis and osteoporosis. On examination she has 3 discrete, painful, necrotic skin lesions on her left calf. There is minimal surrounding erythema and her foot appears well-perfused. Peripheral pulses are present.

Blood tests reveal:

Adjusted calcium	2.62 mmol/l
Parathyroid hormone	47 pmol/l

Which of her regular medications is contributing to her acute presentation?

<input type="checkbox"/>	Sevelamer
<input type="checkbox"/>	Methotrexate
<input type="checkbox"/>	Hydroxychloroquine
<input type="checkbox"/>	Warfarin
<input type="checkbox"/>	Ferrous fumarate

□ Question 18 of 144

You are called to the haematology ward during an evening on-call to review an elective chemotherapy patient. A 23-year-old male was electively admitted to start chemotherapy for Hodgkin's lymphoma the following day and is reporting pain in his left flank. He is currently under investigation by the renal physicians for deteriorating creatinine of unknown cause for the past 4 months, does not take regular medications, smokes about 10 cigarettes every day and occasionally smokes marijuana.

On examination, the patient has bilateral lower limb non-pitting oedema to knees. You note a left varicocele and mild bilateral scrotal oedema. His heart sounds and auscultation of his chest is unremarkable. Abdominal examination reveals only mild left renal angle tenderness. A urine dip reveals 4+ blood, 2+ protein, normal pH. On review of his old clinic letters, you note a renal biopsy from 2 months prior to show IgG and complement deposits on the basement membrane.

His current serum results are:

K ⁺	5.4 mmol/l
Urea	12.8 mmol/l
Creatinine	212 µmol/l
Albumin	18 g/l

What is the most likely acute diagnosis?

	Renal vein thrombosis
	Renal calculus
	IgA nephropathy
	Anti-glomerular basement membrane disease
	Membranoproliferative glomerulonephritis

Overall score: **0%**

Question 18 of 144

You are called to the haematology ward during the night. A 55-year-old male was electively admitted to start chemotherapy for his pancreatic cancer. He has been experiencing severe pain in his left flank. He is currently under investigation for the cause of the pain for the past 4 months, does not take regular painkillers, does not smoke, does not drink alcohol, and does not take recreational drugs.

On examination, the patient has bilateral lower abdominal tenderness. His heart sounds and lungs are normal. His blood pressure is 120/80 mmHg. A urine dipstick shows blood and protein. A renal biopsy from 2 months ago showed glomerular disease.

His current serum results are:

K ⁺	5.4 mmol/l
Urea	12.8 mmol/l
Creatinine	212 µmol/l
Albumin	18 g/l

What is the most likely acute diagnosis?

<input checked="" type="radio"/>	Renal vein thrombosis
<input type="radio"/>	Renal calculus

Question 19 of 144

A 78-year-old female presents to the Emergency Department with confusion, nausea and vomiting. She has been generally unwell with fatigue, weakness and fevers for 4 weeks. On examination her respiratory rate is 26/min, oxygen saturations are 98% on 4 litres of oxygen, blood pressure 100/65 mmHg, pulse 120/min and temperature is 36.3°C. Her airway is patent and crepitations are present at both bases. There are crusting lesions beneath both nostrils, the pulse is thready and regular, heart sounds are normal and her abdomen is soft non-tender. Electrocardiogram shows a sinus tachycardia and urine dip showed 3+ blood and protein. Arterial blood gas on 4 litres of oxygen is as follows:

pH	7.35
pO ₂	7.79 kPa
pCO ₂	3.52 kPa
Bicarbonate	17 mmol/l
Base Excess	-6.9 mmol/l
Lactate	4.5 mmol/l

Venous blood analysis is as follows:

Hb	119 g/l	Na ⁺	129 mmol/l
Platelets	511 * 10 ⁹ /l	K ⁺	6.2 mmol/l
WBC	19.1 * 10 ⁹ /l	Urea	42.1 mmol/l
Neuts	17.2 * 10 ⁹ /l	Creatinine	497 µmol/l
Lymphs	1.8 * 10 ⁹ /l	CRP	241 mg/l
Eosin	0.04 * 10 ⁹ /l		

The patient was resuscitated with fluids and antibiotics although the full septic screen was negative and renal function remained poor. ANA and cANCA pattern were positive with PR3 antibodies found and the renal team were involved. What is the most likely underlying diagnosis?

	Lymphoma
	Churg-Strauss syndrome
	Granulomatosis with polyangiitis
	Acute myeloid leukaemia
	Goodpasture's syndrome

□ □

A 58-year-old Caucasian man with a background of type 2 diabetes mellitus presents to the GP with worsening pedal oedema. On further questioning, he reports having previously had weight loss and alteration in his bowel habit over the past six months.

On examination, he is unkempt, and there is pitting oedema to both thighs and sacral oedema, Lungs are clear, the cardiac examination is unremarkable and the JVP is not elevated. Abdominal exam is unremarkable, as is a digital rectal examination. Urine dip shows protein +++ but is otherwise negative.

Hb	78 g/l	Na ⁺	135 mmol/l	Bilirubin	20 µmol/l
Platelets	340 * 10 ⁹ /l	K ⁺	3.7 mmol/l	ALP	14 u/l
WBC	12 * 10 ⁹ /l	Urea	6 mmol/l	ALT	80 u/l
Neuts	3 * 10 ⁹ /l	Creatinine	67 µmol/l	gamma#GT	30 u/l
Lymphs	7 * 10 ⁹ /l			Albumin	18 g/l
Eosin	0.1 * 10 ⁹ /l	MCV	82 fl		

What is the most likely diagnosis?

	Alcoholic cirrhosis
	Hypoalbuminaemia secondary to poor nutritional status
	Diabetic kidney disease
	Congestive cardiac failure
	Membranous glomerulonephritis secondary to colorectal cancer

□ □

A 39-year-old female with end-stage renal failure secondary to IgA nephropathy is admitted to hospital. She was discharged 3 days earlier following an admission due to collapse in the context of hyperkalaemia (Potassium 7.8 mmol/l). She has been transferred to the medical assessment unit having developed rigors on dialysis earlier today.

Bloods taken at the end of dialysis reveal:

White cell count	15.2 *10 ⁹ /l
Sodium	134 mmol/l
Potassium	2.1 mmol/l
Urea	10.6 mmol/l
Creatinine	400 µmol/l
C-reactive protein (CRP)	119 mg/dL

What is the immediate priority in her management?

	Replace potassium (K ⁺)
	Replace magnesium (Mg ²⁺)
	Intravenous antibiotics
	Intravenous calcium gluconate
	Insulin/dextrose infusion

□ □

You are the medical doctor on an acute medical admissions unit. A 56-year old female with hypertension, pulmonary fibrosis and a recent diagnosis of Raynaud's phenomenon presents with generally feeling unwell. On further questioning she also reports dysphagia for the past few months for which she is awaiting investigations under the gastroenterology team at your hospital. She is currently only on amlodipine 5mg od.

Her observations are: temperature 36.4°C, pulse 88/min, blood pressure 172/88 mmHg, respiratory rate 14/min, sats 100% on room air. Her chest is clear and abdomen soft, non-tender. Blood tests reveal an acute kidney injury with: sodium 141 mmol/l, potassium 4.6 mmol/l, urea 27 mmol/l, creatinine 320 µmol/l (her GP notes state she had a normal renal function from a routine blood test 1 month ago).

What is the most appropriate treatment at this stage?

	Fluids
	Stat 5mg amlodipine
	Stat angiotensin-converting enzyme inhibitor (ACE-i)
	Haemodialysis
	Haemofiltration

Question 25 of 144

□ □

You are the medical doctor on an acute medical admissions unit. A 38-year old female with hypertension is referred by her GP for renal impairment which was found on a routine blood test. She feels well and denies any diarrhoea or vomiting. Her examination was normal and observations reveal a slightly raised blood pressure of 148/86 mmHg. She is usually on ramipril 5mg od and has been taking it for the past 3 years, since her diagnosis of hypertension. The last ultrasound of her kidneys was 2 months ago and it was reported as normal.

Blood tests:

Na ⁺	141 mmol/l
K ⁺	4.6 mmol/l
Urea	11.2 mmol/l
Creatinine	182 µmol/l (baseline 54)
eGFR	52 ml/min (baseline > 90)

What is the most likely cause for her presentation?

	Side effect of ramipril
	Cushing's syndrome
	Conn's syndrome
	Fibromuscular dysplasia
	Hypertensive nephropathy

Overall score: **0%**

Question 26 of 144

A 25 year-old man is referred by his GP with a four week history of bilateral pitting oedema of his legs up to his knees. The only other symptoms he has noticed is some puffiness around the eyes that occurs several times a week and lasts a couple of hours each time. He has no past medical history and reports no rash or musculoskeletal problems. He also has no family history.

Examination reveals bilateral pitting oedema of the legs up to the knees, facial oedema and mild ascites.

Blood tests reveal:

Na ⁺	135 mmol/l
K ⁺	3.4 mmol/l
Urea	4.1 mmol/l
Creatinine	71 µmol/l
Albumin	18 g/l
Cholesterol	11.2 mmol/l

What is the most likely cause of this patient's symptoms?

<input type="checkbox"/>	IgA nephropathy
<input type="checkbox"/>	Post-infectious glomerulonephritis
<input type="checkbox"/>	Minimal change disease
<input type="checkbox"/>	Systemic lupus erythematosus
<input type="checkbox"/>	Diabetic nephropathy

□ Question 27 of 144

A 32 year old man attended his GP feeling generally unwell with headaches and nasal congestion. These symptoms had been ongoing for 4 weeks and did not seem to be responding to over-the-counter decongestants and flu remedies. He also had recurrent nose bleeds and had coughed up fresh blood on two or three occasions. On further questioning he also had some night sweats. He had otherwise been well with no past medical history and took no regular medications.

His GP was concerned about his symptoms and took some blood tests:

Haemoglobin	97 g/L	Sodium	138 mmol/L
Platelets	$169 \times 10^9/L$	Potassium	5.8 mmol/L
White cell count	$10.0 \times 10^9/L$	Urea	13.5 mmol/L
Neutrophils	$5.5 \times 10^9/L$	Creatinine	367 micromol/L
Eosinophils	$0.3 \times 10^9/L$	Albumin	32 g/L
ESR	19 mm/h	Bilirubin	8 micromol/L
CRP	24 mg/L	ALT	27 iu/L
Alkaline Phosphatase	35 iu/L		

On receiving these results the GP admitted the patient to hospital to investigate reasons for the raised creatinine. Additional tests showed:

Urine dip	protein +++ and blood ++
Urinary protein creatinine ratio (PCR)	224

Chest X-ray multiple, well demarcated and round lesions in both lungfields

c-ANCA	positive with high PR3 titres
p-ANCA	negative

Anti-glomerular basement membrane (Anti-GBM) antibodies	negative
Compliment levels	normal

Given the most likely diagnosis, what type of glomerulonephritis (GN) would you expect to see on a renal biopsy?

<input type="radio"/>	Membranous GN
<input type="radio"/>	Diffuse proliferative GN
<input type="radio"/>	Focal segmental glomerulosclerosis
<input type="radio"/>	Rapidly progressive GN
<input type="radio"/>	Membranoproliferative GN

□ Question 27 of 144

A 32 year old man attended his GP feeling general malaise and weight loss, which have been ongoing for 4 weeks and did not seem to be related to any specific illness. He also had recurrent nose bleeds and had cough and sputum production. He also had some night sweats. He had otherwise no other symptoms.

His GP was concerned about his symptoms and ordered a blood test.

Haemoglobin	97 g/L	Sodium	135 mmol/L
Platelets	169 $\times 10^9/L$	Potassium	4.2 mmol/L
White cell count	10.0 $\times 10^9/L$	Urea	12 mmol/L
Neutrophils	5.5 $\times 10^9/L$	Creatinine	350 $\mu\text{mol/L}$
Eosinophils	0.3 $\times 10^9/L$	Albumin	32 g/L
ESR	19 mm/h	Bilirubin	8 micromol/L
CRP	24 mg/L	ALT	27 iu/L
Alkaline Phosphatase	35 iu/L

□ Question 28 of 144

A 64-year-old gentleman was seen in the renal patient clinic. He had a known history of polycystic kidneys and for the last nine months was undergoing haemodialysis. He complained of increasing shortness of breath on exertion over the last few weeks with a reduced appetite. He was assessed by his GP who undertook the following investigations:

Results (16 weeks ago):

Hb	96 g/l
Platelets	$242 \times 10^9/l$
WBC	$6.6 \times 10^9/l$
Ferritin	22 (NR 15-250 mcg/l)
B12	322 (NR 160-900 ng/l)
Folate	18 (NR 3-20 mcg/l)

Na ⁺	136 mmol/l
K ⁺	4.8 mmol/l
Urea	22.2 mmol/l
Creatinine	468 μ mol/l

Upper GI endoscopy: hiatus hernia seen

Lower GI endoscopy: NAD

He was subsequently commenced on ferrous sulphate 200mg TDS by his GP, but did not feel much better. His past medical history comprised diabetes mellitus, hypertension and hypercholesterolaemia for which he was prescribed aspirin 75mg OD, simvastatin 40mg ON, ramipril 5mg OD, amlodipine 5mg OD and gliclazide 80mg OD.

Examination revealed the presence of a pale gentleman with a blood pressure of 132/78 mmHg, heart rate 82 bpm and respiratory rate of 18/min. Examination of his cardiovascular and respiratory systems revealed the presence of a JVP

3cm and an absence of pedal oedema with good air entry in all zones. Examination of his abdomen revealed the presence of two ballotable masses in the renal angle but otherwise no masses and auscultation was unremarkable.

Investigations undertaken at the clinic revealed the following results:

Hb	101 g/l
Platelets	222 * 10 ⁹ /l
WBC	7.2 * 10 ⁹ /l
Ferritin	76 (NR 15-250 mcg/l)
Transferrin saturation	18%
B12	342 (NR 160-900 ng/l)
Folate	17 (NR 3-20 mcg/l)

Na ⁺	136 mmol/l
K ⁺	4.6 mmol/l
Urea	25.2 mmol/l
Creatinine	512 µmol/l
TSH	1.2 mu/l

What is the single next best management step?

	Continue oral iron therapy and recheck FBC, ferritin and transferrin saturation in four weeks
	Commence intravenous iron therapy
	Arrange referral to gastroenterology and haematology for further investigation
	Commence erythropoietin therapy
	Arrange packed red cell transfusion

□ Question 30 of 144

A 46-year-old male was admitted to the Emergency Department with a five-day history of feeling generally unwell. He was unable to identify the exact cause of the illness, except that he had a sore throat a couple of weeks ago which spontaneously resolved. Over the last few hours, he has had three episodes of frank haematuria. Since then he has rapidly deteriorated, with a reducing urine output. His past medical history included hypertension for which he was treated with ramipril 5mg OD. He recalled being under the care of the paediatric nephrology as a child for isolated proteinuria for which no cause was found. He also had cochlear implants fitted as a child for hearing impairment but was otherwise fit and well. Upon specific questioning, he admitted that his mother was also under the care of the nephrology team for sporadic haematuria for which no cause was found, and as far as he was aware of her renal function was normal. He smoked 20 cigarettes per day and consumed 15 units of alcohol per week.

On examination, he was unwell with a heart rate of 125/min, respiratory rate of 28/min and blood pressure 96/74 mmHg. Examination of the cardiovascular system revealed a reduced JVP and skin turgor, and the presence of bilateral pedal oedema. Examination of his respiratory rate revealed tachypnoea but was otherwise unremarkable, with an oxygen saturation of 97% on air. Examination of his gastrointestinal system was unremarkable, as was the examination of his neurological system.

Initial investigations revealed the following:

Na ⁺	129 mmol/l
K ⁺	6.8 mmol/l
Urea	22.1 mmol/l
Creatinine	465 µmol/l

Bilirubin	11 µmol/l
ALP	101 u/l
ALT	22 u/l
Albumin	30 g/l

Urinalysis: blood +++++, protein +++++, leuc/nit negative gluc negative

ECG: HR 126bpm normal sinus tachycardia, tented T waves, QRS interval 132ms
Chest x-ray: unremarkable

The urea and electrolytes 6 months ago were as follows:

Na ⁺	132 mmol/l
K ⁺	5.3 mmol/l
Urea	11.2 mmol/l
Creatinine	138 µmol/l

What is the most likely diagnosis?

	Post streptococcal glomerulonephritis
	Autosomal dominant polycystic kidneys
	Goodpasture's syndrome
	Alport's syndrome
	Granulomatosis with polyangiitis

□ Question 31 of 144

A 25 year old man was admitted under section to an inpatient psychiatric hospital after a severe manic episode. The patient had suffered several previous episodes of depression but had not previously been admitted to hospital for a mental health problem. Treatment for bipolar affective disorder with lithium, lorazepam and olanzapine had been initiated.

Shortly after admission, routine blood tests showed the patient to be hyponatraemic and he was noted to be passing large volumes of urine by ward staff. Following advice from the endocrine team, basic investigations were requested as detailed below.

Sodium	129 mmol / L
Potassium	3.7 mmol / L
Urea	1.8 mmol / L
Creatinine	55 micromol / L
Calcium (adjusted)	2.41 mmol / L (reference 2.20-2.60)
Serum glucose (random)	5.4 mmol / L
Thyroid stimulating hormone	0.8 microU / L (reference 0.4-5.0)
T4 free serum	12.5 pmol / L (reference 8.5-15.2)
Plasma osmolality	265 mmol / L (reference 280-295)
Urine osmolality	80 mmol / L (reference 100-900)
Serum Lithium	0.35 mEq / L (reference 0.8-1.2)

Urine dipstick: negative glucose; negative protein; negative nitrites; negative leucocytes; negative ketones

What is the most likely cause of the patient's polydipsia?

Nephrogenic diabetes insipidus secondary to lithium therapy

	Syndrome of inappropriate anti-diuretic hormone secretion secondary to olanzapine
	Idiopathic cranial diabetes insipidus
	Primary polydipsia
	Excessive alcohol consumption

Question 32 of 144

□ □

A 66-year-old gentleman presents to the emergency department with a fractured humerus following direct trauma. During routine blood tests, it is found that he has stage II chronic renal impairment when compared to previous blood tests. Urinary albumin is found to be within normal range. He has a background of previous ischaemic heart disease and hypertension. His blood pressure ramipril is increased to maximum dose and he is referred to smoking cessation clinic. He is keen to control his blood pressure.

Blood tests:

	01/11/2016	08/09/2016
Na ⁺	144 mmol/l	139 mmol/l
K ⁺	4.8 mmol/l	4.7 mmol/l
Urea	5.2 mmol/l	5.0 mmol/l
Creatinine	112 µmol/l	104 µmol/l

On future review, what should his target blood pressure be in clinic?

	Less than 130/80mmHg
	Less than 135/80mmHg
	Less than 135/85mmHg
	Less than 140/85mmHg
	Less than 140/90mmHg

□ Question 34 of 144

□ □

A 65-year-old woman with end-stage renal failure (ESRF) presents to the renal department with a 2-hour history of severe abdominal pain, vomiting and fever. She was started on peritoneal dialysis 3 months ago which has so far been uneventful. On examination she has a tender and rigid abdomen; bowel sounds are absent. She is pyrexial at 39.5°C and the dialysate drained from her abdomen is cloudy. The peritoneal catheter entry site is clean, dry and non-erythematous.

Investigations:

Peritoneal fluid sample microscopy & culture	Pending
--	---------

What is the most appropriate management?

	Intravenous cefotaxime and metronidazole
	Intravenous piperacillin & tazobactam (tazocin) and gentamicin
	Intravenous flucloxacillin and gentamicin
	Intravenous gentamicin and oral vancomycin
	Intraperitoneal gentamicin and vancomycin

□ Question 35 of 144

You are called to see a 45-year-old male on the renal ward because the nurses are concerned. The gentleman was admitted 2 weeks earlier with acute renal failure. Blood tests revealed a positive anti-neutrophil cytoplasmic antibody (ANCA) with a myeloperoxidase (MPO) level of 131. He underwent renal biopsy 4 days after admission and the provisional pathology report has shown acute crescentic glomerulonephritis (immuno-fluorescence awaited). Five days into admission he developed frank haemoptysis. He was treated with high flow oxygen and did not require transfusion.

You have been asked to see him because he collapsed on the way back from the bathroom. His blood pressure is 85/40 mmHg and he is tachycardic. He looks pale. He denies any further haemoptysis but complains of generalised abdominal pain. Blood results reveal:

White cell count	12.6 *10 ⁹ /l
Haemoglobin	67 g/l
Platelets	129 *10 ⁹ /l
Adjusted calcium	2.01 mmol/l
Prothrombin time	14 seconds
Fibrinogen	1.1 g/dL

An urgent CT angiogram is arranged which confirms intra-abdominal bleeding at the site of his kidney biopsy.

Which treatment is most likely to have increased his risk of delayed post-biopsy bleed?

	Aspirin
	Plasma exchange
	Simvastatin
	Intravenous methylprednisolone

□ Question 36 of 144

A 24-year-old female with a history of sickle cell trait presents to the outpatient department with the results of her routine urine examination which was performed after she complained of an intermittent burning sensation just after passing urine. She works as a fitness instructor at a nearby gym and has said that she takes ibuprofen regularly for recurrent muscle spasms due to exercise. She has no known drug allergies but mentions that she does develop itchy skin and rhinitis when the season changes.

On examination, her blood pressure is 145/95 mmHg and there is mild periorbital puffiness. Her liver is palpable 1 finger breadth below the right costal margin with a total span of 11cms.

Lab results revealed:

Hb	80 g/l
MCV	62 fl
MCH	20 pg
WBC	$9 \times 10^9/l$
Plt	$350 \times 10^9/l$
Urea	8.1 mmol/l
Creatinine	275 μ mol/l
Na+	140 mmol/l
K+	4.1 mmol/l
Albumin	30 g/l

Urine routine examination showed proteinuria 2+

Renal biopsy showed uniform granular capillary wall deposits of IgG and C3 complement.

What is the most appropriate management plan?

	Oral high dose corticosteroids with azathioprine
	Blood pressure control with ACE inhibitors and immunosuppression with chlorambucil/oral prednisolone
	Blood pressure control with ACE inhibitors and plasmapheresis
	Simple observation and regular monitoring of renal functions
	Haemofiltration

□ Question 39 of 144

A 60-year-old woman is seen in an outpatient renal clinic. She has hypertension and has had type 1 diabetes mellitus since the age of 20. She has an eGFR of 15mls/min/1.73m², it is expected that she will need to commence renal replacement therapy in the next year.

She takes the following medications: Atorvastatin 40 mg nocte, ramipril 2.5mg daily, amlodipine 5mg daily, ferrous sulphate 200mg daily and a basal bolus regimen of insulin. She had previously been taking alfacalcidol and calcium acetate but they had been recently stopped.

On examination, she has some pitting ankle oedema up to her mid-tibia, a few bibasal crepitations on examination of her chest and appears comfortable at rest. There are no signs of uraemia.

Investigation results:

Sodium	140 mmol/L
Potassium	5.0 mmol/L
Serum corrected calcium	2.59 mmol/L
Serum phosphate	1.9 mmol/L
Plasma parathyroid hormone concentration	4pmol/L (0.9-5.4)

What would be the most appropriate step to correct the phosphate concentration?

	Start renal replacement therapy now
	Calcium carbonate
	No action needs to be taken
	Sevelamer
	Alendronic acid

Dashboard

Overall score: **0%**

□ Question 40 of 144

□ □

A 74-year-old male is reviewed in the renal outpatient clinic. Over the past 4 years, his renal function has slowly deteriorated, with his creatinine rising to 482 $\mu\text{mol/l}$ and estimated glomerular filtration rate at 7 ml/min. He has noted the amount of urine he passes to be deteriorating over the past 3 months. His past medical history includes hypertension, type 2 diabetes mellitus, duodenal ulcer 35 years ago requiring laparotomy and an incisional hernia that has not been repaired. You discuss renal replacement therapies with him. He is very keen for the least lifestyle-restricting option if at all possible but understands that 'his health comes first'. A recent ultrasound of his renal tract demonstrates bilateral atrophic kidneys with extensive bilateral iliac vessel calcification. What is the most appropriate next treatment?

	Annual follow up
	Haemodialysis
	Peritoneal dialysis
	Renal transplant
	Palliation

Dashboard

Question 41 of 144

A 50-year-old lady presents to the emergency department with transient left sided facial droop and arm weakness lasting 30 minutes with expressive dysphasia which has resolved by the time she arrives in the department. She is referred to the medical team because she has a fever of 38.2 degrees Celsius and has been otherwise generally unwell for the last few days. She is seen by the stroke nurse who arranges for her to have a CT head which is reported as normal. Her blood results are as follows;

Hb	82 g/l
Platelets	$12 \times 10^9/l$
WBC	$5.0 \times 10^9/l$
Neutrophils	$3.0 \times 10^9/l$
Blood film	multiple red cells fragments

Na ⁺	138 mmol/l
K ⁺	4.8 mmol/l
Urea	8.0 mmol/l
Creatinine	180 μ mol/l

Bilirubin	78 μ mol/l
ALP	78 u/l
ALT	40 u/l
Albumin	38 g/l

She is transferred to the acute medical unit. Whilst on the ward awaiting a haematology review for her low platelets and anaemia she suffers another TIA. Given the likely cause of her symptoms, what is the most appropriate treatment?

	Aspirin
	Methylprednisolone and plasma exchange
	Thrombolysis
	High dose cyclophosphamide
	Haemodialysis

□ Question 42 of 144

A 74 year old lady with a background of type 2 diabetes mellitus, hypertension and previous myocardial infarction presents to the Emergency Department with a 2 day history of abdominal pain and profuse diarrhoea which has become bloody in the last 24 hours. Her temperature is 37.2°, heart rate 102 beats per minute and blood pressure 106/74 mmHg. On examination her heart sounds are normal, chest is clear and she has a diffusely tender abdomen.

Hb	10.4 g/dl
Platelets	64 * 10 ⁹ /l
WBC	14.2 * 10 ⁹ /l
Urea	10 mmol/l
Creatinine	154 µmol/l
Bilirubin	56 µmol/l
CRP	125 mg/l

A blood film shows fragmented red blood cells. Given the most likely diagnosis, what is the most appropriate management for this patient?

	Loperamide and IV metronidazole
	Supportive management and notify a consultant in communicable disease control
	Urgent plasma exchange
	Platelet transfusion
	Loperamide and PO ciprofloxacin

Overall score: **0%**

□ Question 43 of 144

□ □

A 52-year-old gentleman complains of severe abdominal pain. He has a background of stage III chronic kidney disease, aspergillosis, type two diabetes mellitus and peripheral vascular disease. Following review by the surgical team, a contrast CT scan is booked. He takes aspirin, clopidogrel, metformin, paracetamol, amphotericin B and insulin. His capillary blood glucose is 8.2mmol/L. He is given IV 0.9% saline and is prescribed to have this before and following contrast. His metformin is also stopped.

Blood tests:

Na ⁺	139 mmol/l
K ⁺	4.1 mmol/l
Urea	5.2 mmol/l
Creatinine	145 µmol/l

Which additional measure is most likely to be effective in preventing contrast-induced acute kidney injury?

	Start insulin sliding scale
	Stop paracetamol
	Give contrast intra-arterially
	Stop amphotericin
	Stop aspirin

Question 44 of 144

A 42-year-old woman with a history of systemic lupus erythematosus comes to the clinic for review. She has been managed over the past few months for class III lupus nephritis with steroids and cyclophosphamide. Her creatinine has stabilised and has remained at 165 $\mu\text{mol/l}$ over the past 2 months. Which of the following is the most appropriate long-term steroid sparing agent with respect to maintaining renal function?

	Mycophenolate mofetil
	Methotrexate
	Azathioprine
	Hydroxychloroquine
	Sulphasalazine

□ Question 45 of 144

A 65-year-old man attends renal transplant clinic as part of the preliminary workup to be considered as a living kidney donor. The patient's 26-year-old daughter has stage 5 chronic kidney disease secondary to congenital hydronephrosis, and will shortly require dialysis unless she receives a donated kidney. Upon arrival at the appointment, the patient states that he is very hopeful that he will be found to be a suitable kidney donor for his daughter.

The patient reports that he is in good general health, with his only active health problem being high blood pressure diagnosed 4 years previously, and for which he is prescribed medications. The patient denies any history of cardiovascular disease, malignancy, chronic infection, nephrolithiasis or kidney disease. There is no history of the patient suffering from any substance misuse or mental health problems.

The patient's regular medications were ramipril 5 mg once daily, amlodipine 10 mg once daily and bendroflumethiazide 2.5 mg daily. He stated that he had no known drug allergies and had never had an adverse reactive to anaesthetic medications. The patient is a lifelong non-smoker.

Examination revealed a moderately overweight but otherwise generally healthy middle-aged man. Cardiovascular, respiratory and abdominal examinations were unremarkable.

Initial investigations undertaken prior to the clinic, together with some details of the proposed recipient of the patient's kidney, are given below.

Body mass index	31.2 kg / m ²
Haemoglobin	160 g / dL
Mean cell volume	89.8 fl
White cell count	7.3 x 10 ⁹ / microlitre
Neutrophils	4.7 x 10 ⁹ / microlitre (reference 1.8-7.8)
Platelets	387 x 10 ⁹ / microlitre
Urea	6.4 mmol / L
Creatinine	103 micromol / L
eGFR	79 ml / min / 1.73 m ²

Sodium	140 mmol / L
Potassium	3.9 mmol / L
Albumin	46 g / L (reference 35-50)
Bilirubin	24 micromol / L (reference < 26)
Urinalysis	no abnormality detected
Urine microscopy	no abnormality detected
Albumin-creatinine ratio	2.8 mg / mmol (reference < 3)
Ambulatory blood pressure monitoring average	158 / 92 mmHg

Potential donor blood type	Potential recipient blood type
Rhesus-D negative	Rhesus-D positive
ABO group A	ABO group AB

What is the absolute contraindication to this patient acting as a living kidney donor to his daughter?

	Uncontrolled hypertension
	Age > 60 years
	Blood type incompatibility
	Impaired renal function
	Obesity

Question 46 of 144

□ □

A 71-year-old patient with end-stage renal failure secondary to adult polycystic kidney disease presents with new painful necrotic skin lesions. Her general practitioner has referred her to hospital as they have failed to improve with oral antibiotics.

On arrival she is afebrile. A bruit and thrill were noted over a left brachiocephalic fistula. She has an irregular 8cm x 4 cm, punched-out ulcer on the medial aspect of her left calf just below her knee. The centre of the ulcer is black and necrotic. There is minimal surrounding erythema.

Bloods results revealed:

White cell count	10.0 * 10 ⁹ /l
C-reactive protein (CRP)	17 mg/dL

Which investigation will confirm the diagnosis?

	Skin swab
	Parathyroid hormone (PTH)
	Skin biopsy
	Anti-neutrophil cytoplasmic antibody (ANCA)
	Computer tomography angiogram of left leg

□ Question 47 of 144

□ □

A 17 year old female patient presents to the acute medical unit with a seizure. She has no past medical history of note. On assessment, she is post-ictal but maintaining airway, breathing, circulation independently. Her capillary blood glucose is 5.4.

CT brain reveals no bleed, no infarct and no space occupying lesion.
ECG: normal sinus rhythm

Bloods are as follows:

Hb	130 g/dl
Plt	$60 \times 10^9/l$
WCC	$14.5 \times 10^9/l$
Na+	133 mmol/l
K+	5.5 mmol/l
Ur	39 mmol/l
Cr	1001 $\mu\text{mol/l}$

Blood gas analysis:

pH	7.34
pCO ₂	4.0 kPa
pO ₂	13.0 kPa
BE	-4 mmol/l
HCO ₃ ⁻	16 mEq/l

You note her renal function and arrange for further investigation by booking a renal ultrasound and performing

immunology bloods to assess for the underlying cause. You catheterise the patient - urine dipstick shows PRO +++, BLD ++. Therefore, a mid-stream sample of urine is sent for microscopy, culture and sensitivity(results awaited). Following discussion with the renal team, the decision is made to dialyse the patient.

Which of the following is an indication for dialysis?

	Creatinine >1000 µmol/l
	pH 7.34
	Potassium >= 5.5 mmol/l
	Urea > 25 mmol/l
	Seizure

□ Question 48 of 144

An 18-year-old male presented to the Emergency Department complaining of blood in his urine for the last day. He described it initially as few drops of dark blood at the end of micturition but has gradually worsened such that at the time of admission he was passing large amounts of cola coloured urine. He also complained of swollen ankles and puffy eyes developing over the last few hours and had been feeling increasing lethargic and unwell over the last two days. When questioned specifically he denied the presence of shortness of breath, chest pain, haemoptysis, previous haematuria or change in urine volume and had otherwise been well in himself. He had no previous renal problems, though he recalled that his brother had been prescribed a course of steroids when he was aged nine years old for leaky kidneys. Other than a one week course of phenoxymethylpenicillin 500mg QDS prescribed by his GP two weeks ago for tonsillitis and a one week course of amoxicillin 500mg TDS prescribed 6 months ago for acute sinusitis he had no drug history and no past medical history of note.

Examination revealed the presence of a young athletic male with a blood pressure of 162/84 mmHg, heart rate of 96bpm, respiratory rate of 18/min, oxygen saturations of 95% on air and temperature of 37.1 Celsius. Examination of the cardiovascular system revealed the presence of normal heart sounds, a JVP of 3cm and the presence of bilateral pitting oedema of his ankles. Examination of his respiratory system was unremarkable with no signs of respiratory distress. Examination of his gastrointestinal system was unremarkable. Examination of his face revealed the presence of bilateral periorbital oedema; examination of his ENT and neurological systems were both unremarkable.

Initial investigation revealed the following results:

Hb	132 g/l
Platelets	428* 10 ⁹ /l
WBC	14.2 * 10 ⁹ /l
ESR	26 mm/hr

Na ⁺	138 mmol/l
K ⁺	5.2 mmol/l
Urea	6.4 mmol/l
Creatinine	77 µmol/l
CRP	18 mg/l

--	--

Bilirubin	18 µmol/l
ALP	82 u/l
ALT	21 u/l
Protein	78 g/l
Albumin	39 g/l

Chest x-ray: normal appearance of heart and lung fields

ECG: sinus tachycardia 108bpm

Urinalysis: blood +++++ protein +++++, ketones +, negative all other parameters

Urine MCS: awaiting result

Blood MCS: awaiting result

What is the most likely diagnosis?

	Rapidly progressive glomerulonephritis
	Berger's nephropathy
	Granulomatosis with polyangiitis
	Post streptococcal glomerulonephritis
	Membranous nephropathy

□ Question 49 of 144

□ □

A 62-year-old man is seen in renal transplant clinic. He had a cadaveric kidney transplant 1 years ago that was initially complicated by rejection and has required high dose immunosuppression. He has good graft function with creatinine 121 $\mu\text{mol/l}$ and no proteinuria. He complains of 2 stone weight loss in 2 months and feels tired.

There is a large painless lymph node in his right axilla and a palpable node in his left inguinal region.

Hb	8.7 g/dl
Platelets	$195 \times 10^9/\text{l}$
WBC	$6.7 \times 10^9/\text{l}$

Which is the most useful virology test?

	BK virus
	Cytomegalovirus
	Epstein Barr virus
	Hepatitis B
	HIV

□ Question 50 of 144

□ □

A 47-year-old lady presented to the Emergency Department with a three-day history of rapid deterioration. She complained of feeling unwell for the last three days with extreme fatigue and reduced appetite, followed by a gradual but rapid onset of swelling in both her legs. She complained further of changes in her urine over the last few days, stating that it appeared frothy and over the last day noticed the presence of blood in her urine, but she denied the presence of urinary frequency, urgency or dysuria. She complained of feeling short of breath on exertion but not at rest and did not suffer from chest pain. She had a past medical history comprising SLE which was diagnosed 12 years ago and hypertension for which she was prescribed ramipril 10mg OD, azathioprine 50mg OD, methotrexate 20mg once per week and folic acid 5mg once per week.

Examination revealed the presence of an unwell lady with a blood pressure of 166/86 mmHg, heart rate of 102, a temperature of 37.1 Celsius and respiratory rate of 22/min. Examination of her cardiovascular system revealed the presence of gross bilateral pitting oedema in her lower limbs to the level of her mid shins, with a JVP of 3cm and normal heart and breath sounds. Examination of her gastrointestinal system was unremarkable.

Initial investigations reveal the following results. Results from DMARD monitoring bloods 2 months ago are shown in brackets.

Hb	122 g/l (126)
Platelets	242 * 10 ⁹ /l (248)
WBC	7.8 * 10 ⁹ /l (8.2)
ESR	26 mm/hr

Na ⁺	131 mmol/l (138)
K ⁺	6.2 mmol/l (5.2)
Urea	22.2 mmol/l (6.4)
Creatinine	268 µmol/l (77)
CRP	42 mg/l

--	--

Bilirubin	18 µmol/l (18)
ALP	76 u/l (82)
ALT	72 u/l (21)
Total protein	52 g/l (78)
Albumin	18 g/l (39)
Glucose	8.2 mmol/l

Chest x-ray: normal heart size and lung fields

ECG: sinus tachycardia 108bpm no acute changes

Urinalysis: blood ++, protein +++++, leuc trace, nit negative, gluc negative, ketone trace

What is the most likely diagnosis?

<input type="radio"/>	Berger's nephropathy
<input type="radio"/>	Membranous glomerulonephritis
<input type="radio"/>	Focal segmental glomerulosclerosis
<input type="radio"/>	Rapidly progressive glomerulonephritis
<input type="radio"/>	Mesangiocapillary glomerulonephritis

□ Question 51 of 144

A 51-year-old gentleman presents to the Emergency Department with a 4-hour history of severe left-sided flank pain. The pain is constant, but waxes and wanes and is associated with multiple episodes of vomiting.

His past medical history is remarkable for congestive cardiac failure, gout, and glaucoma. He has also recently been diagnosed with HIV and started highly active antiretroviral treatment (HAART) 6 months ago.

On examination, the patient is afebrile. His pulse is 96bpm and his blood pressure is 142/79mmHg. His chest is clear and his abdomen is soft, with left-sided costovertebral angle tenderness evident on palpation.

His urine dipstick is as follows:

pH	6.0
Specific gravity	1.020
Blood	+++
Protein	+

A CT KUB is requested and demonstrates inflammatory stranding around the left kidney with mild hydronephrosis but no obvious ureteric calculi.

The patient is admitted for analgesia and hydration but remains symptomatic over the next 24 hours. He undergoes intravenous pyelography which demonstrates a filling defect in the mid-ureter.

Which of the following medications is most likely to be responsible for his symptoms?

	Acetazolamide
	Furosemide
	Tenofovir
	Indinavir

	Allopurinol

□ Question 55 of 144

A 50 year-old man presents with right flank pain. The pain is 9/10 on the pain scale, and does not radiate anywhere. He has also suffered from thirst, polyuria and fatigue, which he has put down to stress from being off work due to a history of chronic lumbar back pain. He has a smoking history of 10 pack years and drinks on average a couple of pints of beer at the weekends. He has no relevant family history. On examination, he has tenderness in the right flank and lower back and his blood pressure is 149/92 mmHg.

Blood tests reveal:

Hb	9.9 g/dL
Platelets	284 * 10 ⁹ /l
WBC	10.5 * 10 ⁹ /l
Mean corpuscular volume	86 fl
Na ⁺	129 mmol/l
K ⁺	3.9 mmol/l
Urea	16.3 mmol/l
Creatinine	410 µmol/l
Calcium	2.19 mmol/l
Phosphate	1.79 mmol/l
Uric acid	0.40 mmol/l

Urinalysis reveals protein ++, leucocytes +. Microscopy reveals renal papillary cells and casts. No organisms are identified.

A plain abdominal x-ray is negative for calculi and calcification. Intravenous urogram reveals clubbed calyces and ring signs.

What is the most likely diagnosis?

	Renal calculi
	Acute interstitial nephritis
	Pyelonephritis
	Analgesic nephropathy
	Acute tubular necrosis

Question 56 of 144

A 55-year-old woman with a background of long-standing rheumatoid arthritis presents with worsening fatigue and weight loss, diarrhoea, and leg swelling. Additionally, she mentions pain in her wrists with 'pins and needles' at the tips of thumb and first two digits, which bothers her at night.

On examination she has waxy skin plaques about the axillary folds, macroglossia, hepatosplenomegaly, pitting oedema of the legs, and peripheral neuropathy. The faecal occult blood test is positive. Serum chemistry noted only mild hypoalbuminaemia. Urinalysis shows proteinuria with no haematuria.

Which of the following is the most appropriate next step in diagnosis?

	Serum protein electrophoresis
	X-ray of vertebral column and skull
	Biopsy of skin, rectal mucosa, or abdominal fat
	Renal biopsy
	Endomyocardial biopsy

Dashboard

Question 57 of 144

A 38 year-old man presented to his GP with weakness and arthralgia. He had a past history of liver cirrhosis secondary to hepatitis C virus infection which was contracted 10 years ago, however he had failed to attend any clinic appointments over the past 18 months.

On examination, his pulse was 85 beats per minute and his blood pressure was 140/80 mmHg. There was a purpuric rash affecting his lower limbs. Urinalysis showed blood 2+ and protein 2+.

Hb	128 g/l
Platelets	$577 \times 10^9/l$
WBC	$10.9 \times 10^9/l$

Na ⁺	137 mmol/l
K ⁺	4.1 mmol/l
Urea	7.3 mmol/l
Creatinine	186 μ mol/l

What is the most important diagnostic investigation?

<input type="checkbox"/>	Antinuclear antibodies
<input type="checkbox"/>	Anti glomerular basement membrane antibodies
<input type="checkbox"/>	Anti-neutrophil cytoplasmic antibodies
<input type="checkbox"/>	Serum cryoglobulins
<input type="checkbox"/>	Antistreptolysin O titre

□ Question 58 of 144

A 64-year-old male Jehovah's witness was brought into hospital two days ago by his wife after increasing generalised fatigue and malaise over the past 4 weeks. Today, he has been unable to get out of bed. His past medical history includes stage 5 chronic kidney disease, hypertension and type 2 diabetes. He continues to pass urine without renal replacement therapy with a baseline creatinine of 260 $\mu\text{mol/l}$. On examination, he is warm peripherally with conjunctival pallor. His heart sounds are unremarkable, the chest is clear and abdomen soft and non-tender. He has passed 800mls of urine in the last 24 hours. His blood tests are as follows:

Hb	80 g/l
Platelets	$201 \times 10^9/\text{l}$
WBC	$6.7 \times 10^9/\text{l}$
Ferritin	4 ng/ml
Transferrin saturation	19%

Na^+	145 mmol/l
K^+	4.9 mmol/l
Urea	17.7 mmol/l
Creatinine	276 $\mu\text{mol/l}$

What is the most appropriate management?

	Intravenous blood transfusion
	Haemofiltration
	Intravenous iron supplement
	Intravenous erythropoietin

□ Question 59 of 144

□ □

A 65-year-old woman is investigated for intermittent visible haematuria. Her symptoms have been present for around 6 weeks and are associated with a dull ache in the right loin area. Her past medical history includes depression, hypertension and lower back pain. She has no history of urinary problems other than recurrent bouts of 'cystitis'. Blood tests show the following:

Hb	12.2 g/dl	Na ⁺	142 mmol/l
Platelets	389 * 10 ⁹ /l	K ⁺	3.9 mmol/l
WBC	8.2 * 10 ⁹ /l	Urea	6.5 mmol/l
		Creatinine	90 µmol/l
		CRP	14 mg/l

A CT is requested:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Chronic pyelonephritis with abscess formation
	Wilm's tumour
	Renal cyst
	Autosomal dominant polycystic kidney disease
	Renal cell cancer

□ Question 60 of 144

A 58-year-old lady with an extensive psychiatric history presents to the Acute Medical unit unwell and dehydrated. She recently had a viral illness and has spent most of the past week in bed. She is mildly confused on arrival and the ambulance sheet states that for the past two weeks she has been passing urine more frequently, particularly at night. She denies any dysuria or fevers.

She has a history of bipolar affective disorder which is currently stable on lithium. She also has a history of irritable bowel syndrome, hypertension, hypercholesterolaemia and migraines. She currently takes amlodipine 10mg once a day, simvastatin 20mg at night, mebeverine 135mg three times a day and lithium carbonate 800mg at night. She has no known drug allergies.

On examination, she looks unwell and dehydrated. Her pulse is 105 bpm and regular, blood pressure 95/65 mmHg, saturations of 98% on air. Numerous linear scars are apparent on both her arms and the tops of her thighs. Her mucous membranes are dry and her JVP is not visible at 45 degrees. Her chest was clear. Abdominal examination demonstrated a soft, non-tender abdomen with no masses or organomegaly and normal bowel sounds.

A set of bloods come back as follows:

Na ⁺	153 mmol/L
K ⁺	4.9 mmol/L
Urea	8 mmol/L
Creatinine	110 µmol/L
Hb	160 g/L
WBC	$6.0 \times 10^9/L$
LFTs	Normal
Urine osmolality	180 mOsmol/kg

Chest x-ray shows clear lung fields.

Considering the most likely diagnosis which of the following treatments are most likely to treat the underlying condition?

	Hypertonic saline resuscitation
	Low dose DDAVP
	Observation
	Thiazide diuretic and amiloride
	1.5L fluid restriction

□ Question 64 of 144

A 56-year-old gentleman was admitted to the Emergency Department with a two-week history of progressively increasing shortness of breath, with frank haemoptysis for the last couple of days. He had recently returned from a holiday in Turkey a few weeks ago. By the point of admission, he was short of breath on minimal exertion and at rest and was unable to complete full sentences. He also complained of increasing orthopnoea for the last few weeks. He had a long history of recurrent epistaxis, rhinitis and sinusitis, as well as a past medical history of diabetes, hypertension, hypercholesterolaemia and gout. His medication regimen comprised of mometasone nasal spray, allopurinol 100mg OD, ramipril 2.5 mg OD, amlodipine 5mg OD, simvastatin 40mg OD, metformin 500mg TDS and gliclazide 80mg OD. He smoked 20 cigarettes per day and did not consume alcohol.

On examination, he appeared very unwell with obvious respiratory distress. His respiratory rate was 28/min, his oxygen saturations were 90% on air, his blood pressure was 108/72 mmHg, his heart rate was 129 and his temperature was 37.9 degrees celsius. Examination of his cardiovascular system revealed normal heart sounds with a JVP of 3cm. Examination of the respiratory system revealed the use of accessory muscles with bibasal fine crackles. Examination of the gastrointestinal and neurological systems was unremarkable.

Initial investigations revealed the following:

Hb	82 g/l
Platelets	$342 \times 10^9/l$
WBC	$14.2 \times 10^9/l$
ESR	88 mm/hr

Na ⁺	128 mmol/l
K ⁺	6.1 mmol/l
Urea	28 mmol/l
Creatinine	762 μ mol/l
CRP	42 mg/l
Glucose	5.6 mmol/l

Chest x-ray: bilateral patchy infiltration
ECG: heart rate 132 bpm normal sinus rhythm, no other changes
Urinalysis blood ++++ protein +++ leuc/nit negative glucose negative

ABG on 15 l/min oxygen:

PaO2	16.9 kPa
PaCO2	2.8 kPa
HCO3	18.2 mmol/l
pH	7.49

He was catheterized, commenced on an intravenous infusion of normal saline, as well as co-amoxiclav 625mg TDS and quickly transferred to the Intensive Care Unit. A decision was made to institute immediate haemodialysis, for which preparations were being made.

Further investigations revealed the following:

Urine MCS: nil grown
Blood culture - interim results: nil grown

Transoesophageal echocardiogram: normal systolic function, valvular appearances and no vegetations seen

C3	1.22 (NR 0.65 1.65g/L)
C4	0.32 (NR 0.16 0.60 g/L)
ANA	negative
ENA	negative
dsDNA	negative
cANCA	positive
pANCA	negative
Rheumatoid factor	negative

Given the likely underlying diagnosis, which of the following interventions is the next best step whilst awaiting haemodialysis?

	Stop IV augmentin, commence IV meropenem
	Commence IV immunoglobulins
	Commence high dose IV methylprednisolone and cyclophosphamide

	Institute immediate plasma exchange
	Commence intravenous activated protein C

Chest x-ray: bilateral patchy infiltration

ECG: heart rate 132 bpm normal sinus rhythm, no other changes

Urinalysis blood ++++ protein +++ leuc/nit negative glucose negative

ABG on 15 l/min oxygen:

PaO2	16.9 kPa
PaCO2	2.8 kPa
HCO3	18.2 mmol/l
pH	7.49

He was catheterized, commenced on an intravenous infusion of normal saline, as well as co-amoxiclav 625mg TDS and quickly transferred to the Intensive Care Unit. A decision was made to institute immediate haemodialysis, for which preparations were being made.

Further investigations revealed the following:

Urine MCS: nil grown

Blood culture - interim results: nil grown

Transoesophageal echocardiogram: normal systolic function, valvular appearances and no vegetations seen

C3	1.22 (NR 0.65 1.65g/L)
C4	0.32 (NR 0.16 0.60 g/L)
ANA	negative
ENA	negative
dsDNA	negative
cANCA	positive
pANCA	negative
Rheumatoid factor	negative

Given the likely underlying diagnosis, which of the following interventions is the next best step whilst awaiting haemodialysis?

	Stop IV augmentin, commence IV meropenem
	Commence IV immunoglobulins
	Commence high dose IV methylprednisolone and cyclophosphamide
	Institute immediate plasma exchange
	Commence intravenous activated protein C

Overall score: 0%

□ Question 64 of 144

□ □

A 56-year-old gentleman was admitted to the Emergency Department with a two-week history of progressively increasing shortness of breath, with frank haemoptysis for the last couple of days. He had recently returned from a holiday in Turkey a few weeks ago. By the point of admission, he was short of breath on minimal exertion and at rest and was unable to complete full sentences. He also complained of increasing orthopnoea for the last few weeks. He had a long history of recurrent epistaxis, rhinitis and sinusitis, as well as a past medical history of diabetes, hypertension, hypercholesterolaemia and gout. His medication regimen comprised of mometasone nasal spray, allopurinol 100mg OD, ramipril 2.5 mg OD, amlodipine 5mg OD, simvastatin 40mg OD, metformin 500mg TDS and gliclazide 80mg OD. He smoked 20 cigarettes per day and did not consume alcohol.

On examination, he appeared very unwell with obvious respiratory distress. His respiratory rate was 28/min, his oxygen saturations were 90% on air, his blood pressure was 108/72 mmHg, his heart rate was 129 and his temperature was 37.9 degrees celsius. Examination of his cardiovascular system revealed normal heart sounds with a JVP of 3cm. Examination of the respiratory system revealed the use of accessory muscles with bibasal fine crackles. Examination of the gastrointestinal and neurological systems was unremarkable.

Initial investigations revealed the following:

Hb	82 g/l
Platelets	$342 \times 10^9/l$
WBC	$14.2 \times 10^9/l$
ESR	88 mm/hr

Na ⁺	128 mmol/l
K ⁺	6.1 mmol/l
Urea	28 mmol/l
Creatinine	762 µmol/l
CRP	42 mg/l
Glucose	5.6 mmol/l

Chest x-ray: bilateral patchy infiltration

ECG: heart rate 132 bpm normal sinus rhythm, no other changes

Urinalysis blood ++++ protein +++ leuc/nit negative glucose negative

ABG on 15 l/min oxygen:

PaO2	16.9 kPa

Question 65 of 144

□ □

A 77-year-old man has been admitted with an ischaemic right limb and the vascular surgical team would like to perform a CT with contrast to investigate. He has a history of diabetes and heart failure. His blood tests are shown below

Hb	135 g/l
Platelets	$270 \times 10^9/l$
WBC	$6 \times 10^9/l$

Na ⁺	140 mmol/l
K ⁺	4 mmol/l
Urea	6 mmol/l
Creatinine	140 μ mol/l
eGFR	65 ml/min/1.73m ²

What is the best measure to prevent acute kidney injury in this man?

	N-acetylcysteine pre-scan and post-scan
	Oral volume expansion
	N-acetylcysteine pre-scan
	N-acetylcysteine post-scan
	Intravenous volume expansion

Question 66 of 144

□ □

A 19 year-old man presents with frank haematuria. He had just recovered from a severe cold and states that the symptoms of the cold have now resolved. He took paracetamol for the cold and was not prescribed any antibiotics. His past medical history includes hearing problems from a young age, for which he wears hearing aids and a recent corneal ulcer. His observations are stable and urine dipstick reveals protein ++ and blood +++ in his urine.

It is decided that he will undergo a renal biopsy. What is the most likely finding under light microscopy?

	Nothing
	Rapidly progressive glomerulonephritis
	Membranous nephritis
	Mesangiocapillary glomerulonephritis
	Acute tubular necrosis

Dashboard

Question 67 of 144

A 56-year-old male presents with oliguria, fever and proteinuria eight days after renal transplant. On examination, his abdomen is soft and non-tender, the transplant scar has a mild serous ooze but otherwise clean. A urine dip demonstrates protein 4+ blood 1+, urine output over the past 3 hours have been 27, 20 and 12 ml/ hour respectively. His blood tests are as follows (results from 24 hours ago in brackets)

Hb	99	(98) g/dl
Platelets	190	(185) * 10 ⁹ /l
WBC	3.6	(3.6) * 10 ⁹ /l

Na ⁺	139	(136) mmol/l
K ⁺	4.9	(4.6) mmol/l
Urea	19	(7.8) mmol/l
Creatinine	225	(117) µmol/l

A renal ultrasound demonstrates a normal sized transplanted kidney, no ureteric leak and no hydronephrosis. His tacrolimus levels are within normal range. An urgent renal biopsy of the transplanted kidney demonstrates significant lymphocytic, in particular, mononuclear cell infiltration with no clonal populations, EBV antigen negative and no light chains. His CMV titre is negative, his tacrolimus level is therapeutic. What is the most appropriate immediate management?

<input type="checkbox"/>	IV methylprednisolone
<input type="checkbox"/>	Stop tacrolimus
<input type="checkbox"/>	Increase tacrolimus
<input type="checkbox"/>	Percutaneous nephrostomy insertion
<input type="checkbox"/>	Start ciclosporin

□ Question 71 of 144

A 69-year-old-male attends clinic for review. Today he is complaining of fleeting joint pains and a progressive rash on both legs.

He suffers from chronic back pain but hasn't seen his GP, instead, taking over the counter painkillers for the past six weeks. He has a background of hypertension.

On examination, you are unable to find any evidence of active synovitis. You note a symmetrical eruption of palpable, red-purple papular lesions across the extensor surfaces of both legs. He has vesicular breath sounds with oxygen saturations at 99% on room air. His heart sounds are normal, with no murmurs. His clinic blood pressure reading is 146/88 mmHg. His abdomen is soft and non-tender.

Hb	132 g/l	Na ⁺	135 mmol/l
Platelets	155 * 10 ⁹ /l	K ⁺	5.1 mmol/l
WBC	9.9 * 10 ⁹ /l	Urea	7.3 mmol/l
Neuts	5.1 * 10 ⁹ /l	Creatinine	256 µmol/l
Lymphs	1.0 * 10 ⁹ /l	CRP	6 mg/l
Eosin	2.5 * 10 ⁹ /l		

Which of the following is the most likely diagnosis?

	Churg-Strauss syndrome
	Tubulointerstitial nephritis
	Dermatitis herpetiformis
	Hypereosinophilic syndrome
	Cutaneous larva migrans

□ Question 73 of 144

You are the medical registrar on-call. A 70-year-old male presents to the Emergency Department (ED) with clinical findings consistent with critical limb ischaemia. The patient has a background of diabetes and chronic kidney disease (Stage 4). He is admitted under the vascular surgeons who wish to undertake a CT angiogram. They contact you with the following bloods results:

	Today	1 month ago
Na ⁺	141 mmol/l	138 mmol/l
K ⁺	4.7 mmol/l	4.4 mmol/l
Urea	15.8 mmol/l	9.8 mmol/l
Creatinine	241 µmol/l	158 µmol/l

What evidence-based advice should you give to minimise the risk of contrast-induced nephropathy?

	Oral pre-hydration is superior to intravenous pre-hydration
	Intravenous fluids should be administered with a diuretic
	Intravenous N-acetylcysteine is superior to oral N-acetylcysteine
	Prophylactic haemofiltration should be undertaken post-scan
	Intravenous pre- and post-hydration should only be undertaken with isotonic fluid

□ Question 75 of 144

□ □

A 48-year-old caucasian male presents to his general practitioner for a routine check up. He is asymptomatic and has a past medical history of type two diabetes and hypercholesterolaemia. He is a non smoker, does not drink alcohol, and works as a teacher. Currently he takes metformin 500 mg thrice daily, gliclazide 80 mg daily and simvastatin 40 mg nightly. Examination is normal, body mass index is 22 kg/m², blood pressure is 140/78 mmHg and fundoscopy is normal. Urine dip shows protein 2+. Routine bloods show:

Hb	132 g/l	Na ⁺	137 mmol/l
Platelets	204 * 10 ⁹ /l	K ⁺	4.6 mmol/l
WBC	5.6 * 10 ⁹ /l	Urea	5.7 mmol/l
Neuts	4.5 * 10 ⁹ /l	Creatinine	97 µmol/l
Lymphs	1.0 * 10 ⁹ /l	eGFR	62 mg/l
Eosin	0.04 * 10 ⁹ /l	HbA1c	47 mmol/mol

What management changes would you consider?

	Amlodipine 5 mg once daily
	Bendroflumethiazide 2.5 mg once daily
	Increase gliclazide to 80 mg twice daily
	Stop metformin
	Ramipril 2.5 mg once daily

Overall score: **0%**

□ Question 76 of 144

□ □

A 45-year-old teacher is reviewed in a routine nephrology clinic. She has end stage renal failure with focal segmental glomerular sclerosis (FSGS) on biopsy and is receiving renal replacement via haemodialysis. She requires hearing aids for bilateral sensorineural hearing loss and is of short stature. She mentions that she has been feeling more tired and lethargic in the last few months. A fasting blood sugar taken by her GP is 8.0mmol/l. She has a family history of diabetes in her mother and maternal grandmother, both of whom also required hearing aids at an early age. Given the above features, what is the most likely cause of her end stage renal failure?

	Autosomal dominant polycystic kidney disease
	Alport syndrome
	Liddle syndrome
	Maternally inherited diabetes and deafness (MIDD)
	Granulomatosis with polyangiitis (Wegener granulomatosis)

□ Question 77 of 144

A 59 year-old woman presents for her annual diabetic check-up. She has had type 2 diabetes mellitus for 15 years and takes only metformin for the diabetes. Her HbA1c was revealed as being 40 mmol/mol on her last diabetes check-up 1 week ago. Her past medical history includes peripheral vascular disease and migraine. She has a smoking history of 20 pack years and drinks 5-10 units of alcohol per week. On examination, her pulse rate is 86 beats per minute and her blood pressure is 126/70 mmHg and is otherwise unremarkable.

Blood tests reveal:

Na ⁺	140 mmol/l
K ⁺	3.4 mmol/l
Urea	7.0 mmol/l
Creatinine	105 µmol/l

Urinalysis reveals:

Protein	Negative
Glucose	Negative
Leucocytes	Negative
Nitrites	Negative

24-hour urine sample demonstrates 190 mg of albumin in the urine.

What is the most appropriate next management with regards to her renal function?

	Start a beta blocker
	Start an angiotensin II receptor blocker

	Optimise the patient's glycaemic control
	Start an ACE inhibitor
	Start a thiazide diuretic

Dashboard

Question 78 of 144

A 92-year-old lady is admitted to the orthopaedic ward following a fall and lying three hours on the floor. She was brought in by ambulance and diagnosed with a right intertrochanteric fractured neck of femur. She was operated on six hours later and underwent fixation with a dynamic hip screw. She was given two units of blood during surgery.

The next day she reviewed by the orthogeriatric team. Over the last twelve hours, she has passed 337ml of urine. Her creatinine from the day before was 162umol/l. Her baseline creatinine from two months ago was 45umol/l. Her weight is 61kg.

What is the most appropriate description of her current renal function?

	No renal impairment
	Stage I acute kidney injury
	Stage II acute kidney injury
	Stage III acute kidney injury
	Chronic renal disease

Dashboard

Overall score: 0%

□ Question 79 of 144

□ □

A 72-year-old woman is admitted with a cough and fever. She has been unwell for four days with a worsening productive cough, chest pain, fever and shortness of breath. Observations show tachycardia, fever, and hypoxia. She weighs 42kg. A chest x-ray demonstrated right middle lobe consolidation and she is diagnosed with a lower respiratory tract infection and sepsis.

She is given IV fluids, IV antibiotics and a urinary catheter is inserted. She is reviewed at the post-take ward round 8 hours later. Since then she has passed 141ml of urine, which appears dark. You calculate that she is passing urine at a rate of 0.42ml/kg/hr. Creatinine from admission is 87µmol/L. There are no previous levels of creatinine measured.

What is the most appropriate description of her renal function?

	No renal impairment
	Stage I acute kidney injury
	Stage II acute kidney injury
	Stage III acute kidney injury
	Chronic renal disease

□ Question 80 of 144

□ □

You see a 56-year-old female in the renal low clearance clinic with known progressive proteinuric diabetic nephropathy. Despite maximal medical therapy she has had poorly controlled type 1 diabetes since 18 years of age; she also has hypertension and hypercholesterolaemia. She is asymptomatic and feels fit and well but is concerned regarding the deterioration in her kidney function. Cardiovascular, respiratory and abdominal examinations are unremarkable. A sensory peripheral neuropathy, reduced dorsalis pedis pulses bilaterally and pitting oedema to both ankles are noted. Fundoscopy shows evidence of photocoagulation therapy in both eyes. Today's blood results show:

Hb	109 g/l	Na ⁺	129 mmol/l
Platelets	111 * 10 ⁹ /l	K ⁺	5.1 mmol/l
WBC	5.7 * 10 ⁹ /l	Urea	22 mmol/l
Neuts	4.6 * 10 ⁹ /l	Creatinine	259 µmol/l
HbA1c	86 mmol/mol	eGFR	18 ml/min/1.73 ²

Her eGFR 3 months ago was 20. Considering her progressive stage 4 chronic kidney disease what is the gold standard treatment option in this case?

	Haemodialysis
	Combined renal and pancreas transplant
	Peritoneal dialysis
	Pancreas transplant
	Renal transplant

Overall score: **0%**

□ Question 82 of 144

A 44-year-old Greek-Cypriot man is reviewed in the renal outpatient clinic. His renal function has been progressively deteriorating over the past 5 years secondary to poorly controlled type 2 diabetes mellitus. His eGFR is now 7 ml/min but continues to pass urine. Recent ultrasound scans have shown that he would anatomically be suitable for a renal transplant. However, you explain that in the context of his ethnicity, there is an uncertain wait for suitability of organs, should the patient require to proceed down this path. His 15-year-old son, who is present with the patients two daughters and wife, offers his father a donor kidney due to the high likelihood of compatibility, which the patient would like to proceed with.

The father's blood tests are shown below::

Hb	89 g/l
Platelets	178 * 10 ⁹ /l
WBC	6.5 * 10 ⁹ /l

Na ⁺	144 mmol/l
K ⁺	5.3 mmol/l
Urea	18.2 mmol/l
Creatinine	280 µmol/l
pH	7.32

What is the most appropriate next step?

	Monitor renal function, discuss renal replacement therapy in 6 months time
	Start haemodialysis today, discuss renal replacement therapy in 6 months time
	Start preparation for haemodialysis and list for renal transplant on national transplant list

	Start preparation for haemodialysis and list for renal transplant with the patients son's kidney
	Palliation

Question 83 of 144

□ □

A 67-year-old woman with a renal transplant is seen in clinic. She has noted increased swelling of her legs over the past 3 weeks but is relatively well otherwise.

On examination she is hypertensive at 162/110mmHg and has pitting oedema up to the mid shin bilaterally. Urine dip shows protein 3+ and blood 2+, with a serum creatinine of 142umol/l (previously 70umol/l).

A renal biopsy reveals a recurrence of her original disease.

Which disease has the highest rate of recurrence in renal transplant patients?

	Membranoproliferative glomerulonephritis
	IgA nephropathy
	Polycystic kidney disease
	Focal segmental glomerulosclerosis
	Alport's syndrome

Dashboard

□ Question 84 of 144

A 72-year-old man is admitted with sudden onset shortness of breath and haemoptysis, with oxygen saturations of 92% on room air. Two days prior to admission, his general practitioner had prescribed furosemide 40mg once a day for progressive lower limb swelling and fatigue. He was due to see his general practitioner again tomorrow to review the initial blood tests. His past medical history includes systemic hypertension and stage 2 colon cancer treated with surgical resection and adjuvant chemotherapy (15 years ago). He is a current smoker.

An arterial blood gas shows a type 1 respiratory failure, with a pH of 7.31 and a pO₂ of 9.7 kPa. Oxygen saturations of >96% are achieved with four litres of oxygen. A chest x-ray shows alveolar infiltrates within the right lower lobe. Urgent spirometry reveals an increased transfer factor.

Urine dip demonstrates a loss of protein, but no blood, leucocytes or nitrites.

A full panel of bloods, including a full vasculitic screen is requested (see below).

White cells	12.0 × 10 ⁹ /l
Haemoglobin	11.7 g/dl
Sodium	144 mmol/l
Potassium	5.6 mmol/l
Urea	18 mmol/l
Creatinine	240 mol/l
Albumin	19 g/l
ANA	negative
ANCA	negative
Anti-GBM	positive

What is the next management step?

--	--

	Thrombolysis
	Intravenous antibiotics
	Haemodialysis
	Continuous positive airway pressure (CPAP)
	Plasmapheresis

□ Question 86 of 144

A 73 year old gentleman was shown to have left ventricular dysfunction and hypertrophy on an echocardiogram post acute myocardial infarction (MI). Prior to discharge he was started on ramipril 2.5mg, bisoprolol 2.5mg, atorvastatin 10mg and aspirin 75mg. His medical history included osteoporosis for which he took calcichew D3 forte and alendronic acid. He did not smoke or drink alcohol. On admission his kidney function showed the following:

Sodium	136 mmol/L
Potassium	3.7 mmol/L
Urea	7.0 mmol/L
Creatinine	120 micromol/L
eGFR	64 ml/min/1.73m ²

His GP checked his bloods again ten days after the initiation of his new medication to titrate the dose of ramipril as requested on the discharge letter from the cardiology team. The results are below:

Sodium	134 mmol/L
Potassium	4.2 mmol/L
Urea	8.0 mmol/L
Creatinine	156 micromol/L
eGFR	50 ml/min/1.73m ²

How would you manage this gentleman's deteriorating renal function?

	Continue the ramipril and repeat the bloods in one week
	Decrease the dose of ramipril to 1.25mg daily
	Stop the ramipril

	Switch the ramipril to losartan
	Request a renal ultrasound scan

Dashboard

Question 87 of 144

□ □

A 40-year-old man with chronic kidney disease stage 5 secondary to autosomal-dominant polycystic kidney disease is seen in general nephrology clinic. He reports worsening fatigue and denies any alteration in bowel habit or weight loss. Examination demonstrates a blood pressure of 120/56mmHg, heart rate 56bpm, respiratory rate 18/min, Sats 99% on air and he is afebrile. Abdomen is soft on non-tender with bilateral palpable kidneys and a palpable irregular liver edge. He is euvolemic.

Hb	78 g/l
Platelets	167 * 10 ⁹ /l
WBC	7 * 10 ⁹ /l
Ferritin	95 ng/mL

B12 and folate are within normal range.

What is the most appropriate next step?

	Faecal occult blood testing
	Blood transfusion
	Referral for OGD
	Iron transfusion
	Erythropoietin

□ Question 88 of 144

A 39 year-old woman presents with a four month history of abdominal distension, facial swelling and malaise. Her past medical history includes a diagnosis of membranous glomerulonephritis. On examination, heart sounds 1 and 2 were present with no added sounds and the pulse was regular, lung fields were clear, abdominal exam reveals mild ascites and there was bilateral periorbital oedema with pitting oedema of the shins.

Blood tests reveal:

Hb	8.8 g/dL
Platelets	$115 \times 10^9/l$
WBC	$4.2 \times 10^9/l$
Mean corpuscular volume (MCV)	82 fl
Na ⁺	148 mmol/l
K ⁺	3.3 mmol/l
Urea	9.2 mmol/l
Creatinine	176 μ mol/l
Bilirubin	14 μ mol/l
ALP	91 u/l
ALT	19 u/l
γ GT	68 u/l
Albumin	32 g/l
Cholesterol	7.9 mmol/l

Urinalysis reveals protein +++ and a 24-hour protein excretion is 5.2g.

High-dose diuretics and immunosuppression was started. Two weeks later the patient presents with abdominal pain

which is 6/10 on the pain scale and worse in her flanks. Her observations were normal apart from a temperature of 38.3°C. Blood tests are performed and are similar to before except a raised creatinine to 314 µmol/l and a urea of 15.1 mmol/l.

What is the most likely reason this patient has had a deterioration in her renal function?

	Renal infarction
	Renal artery stenosis
	Renal calculus
	Renal vein thrombosis
	Acute pyelonephritis

□ Question 89 of 144

A 48-year-old male presents to his general practitioner with a 3-month history of worsening swelling of both arms and legs. He has chronic lower back pain and has noticed an accidental increase of 4 kg over 2 months. He has a past medical history of ankylosing spondylitis, hypertension and hypercholesterolaemia and currently takes regular paracetamol, amlodipine 5mg OD and simvastatin 40 mg ON. On examination observations are normal, there is a reduction in all spinal movements and pitting oedema to his mid thighs bilaterally; there is no redness, tenderness or heat. His face and arms also appear swollen although no pitting is present. Respiratory, cardiovascular and abdominal examinations are normal.

Urine dip shows 3+ protein nil else and bloods are as follows:

Hb	115 g/l	Na ⁺	139 mmol/l
Platelets	380 * 10 ⁹ /l	K ⁺	4.3 mmol/l
WBC	8.1 * 10 ⁹ /l	Urea	4.2 mmol/l
Neuts	6.2 * 10 ⁹ /l	Creatinine	73 µmol/l
Lymphs	1.8 * 10 ⁹ /l	CRP	49 mg/l
Eosin	0.02 * 10 ⁹ /l	Albumin	25 g/l

What is the most likely cause of this patient's oedema?

	Minimal change nephropathy
	Amlodipine
	AL amyloidosis
	Hypertensive nephropathy
	AA amyloidosis

□ Question 90 of 144

A 62-year-old man attends hospital for an elective laparoscopic inguinal hernia repair. The surgical team note that the patient has impairment of his renal function on pre-operative blood tests and so refer the patient to the on-call general medical registrar. Following the referral, the surgical team were asked to organise some basic further investigations pending a medical review. The patient then underwent the planned surgical procedure, which was apparently uncomplicated and spent the following night in hospital as originally planned.

The day after the patient's operation, the patient was reviewed on the ward by the general medical team. He reported himself to be recovering well from the operation, although he was quite worried about the abnormality uncovered with his kidneys as he had been told he had 'chronic renal failure'. The patient had never previously been aware of any problems involving his kidneys and reported being in good general health, with his only previous medical concerns being well-controlled asthma and the hernia that lead to him being admitted to hospital. He denied any history of diabetes, hypertension, connective tissue disease, renal calculi or prostatic symptoms. There was no family history of kidney disease. The patient took a regular steroid inhaler for his asthma and denied significant use of non-steroidal anti-inflammatory drugs. The patient worked as a supermarket manager and reported smoking a cigar a couple of times per week.

On examination, the patient appeared to be in generally good health. Blood pressure was 128 / 85 mmHg. The patient was euvolaemic, with no evidence of pulmonary oedema or peripheral oedema. Examination of the patient's abdomen was unremarkable, except for the surgical incisions associated with his recent operation. The patient had been catheterised peri-operatively and was documented to be passing appropriate volumes of urine (i.e. > 0.5 ml / kg / hour).

Please see below for investigations arranged after the patient was admitted to hospital. The patient's GP surgery had been contacted but did not have records of any relevant recent blood tests.

Haemoglobin	136 g / dL
Mean cell volume	87.8 fl
White cell count	5.7×10^9 / microlitre
Platelets	238×10^9 / microlitre
Urea	7.9 mmol / L
Creatinine	131 micromol / L

eGFR	57 ml / min / 1.73 m2
Sodium	137 mmol / L
Potassium	4.1 mmol / L
Thyroid stimulating hormone	4.2 microU / mL (reference 0.4-5.0)
Urinalysis	no abnormality detected
Urine microscopy	no abnormality detected
Albumin:creatinine ratio	2.8 mg / mmol (reference < 3)

What is the appropriate classification of the patient's abnormal renal function?

	Chronic kidney disease G2A3
	Chronic kidney disease not confirmed
	Chronic kidney disease G2A1
	Chronic kidney disease G3aA1
	Chronic kidney disease G3bA2

□ Question 91 of 144

A 64-year-old lady was admitted to hospital with haematuria. She had been feeling unwell in the preceding weeks with lethargy, vomiting, weight loss and fevers. A day prior to admission she developed haematuria with reduced urine output. She had no previous medical history but was an ex-smoker. She was fit and active working as a retail shop manager. Examination revealed a pale and lethargic woman with mild peripheral oedema. Her chest was clear, the abdomen was soft and non-tender with no palpable masses.

Investigations:

Urine dip: blood+++, protein++

Haemoglobin	86 g/L
White cell count	$8.7 \times 10^9/\text{L}$
Platelet Count	$201 \times 10^9/\text{L}$
INR	1.0

Serum sodium	139mmol/L
Serum potassium	6.3mmol/L
Serum urea	34.0mmol/L
Serum creatinine	789 micromol/L
CRP	32

Antinuclear antibody	negative
Anti-neutrophil cytoplasmic antibody	negative
Anti-glomerular basement membrane antibody	positive

Chest radiograph: Clear lung fields.

She was diagnosed with renal limited anti-GBM disease and started on methylprednisolone and cyclophosphamide. What other treatment should be initiated?

	Tacrolimus
	Blood transfusion
	IV tazocin
	Plasma exchange
	3-way catheter and bladder irrigation

□ Question 93 of 144

A 25-year-old man attends renal clinic following a referral by his GP due to concerns about recent blood tests suggesting impaired renal function. The patient was a professional rugby player, and as part of pre-season training had undergone a range of screening blood tests. These tests had been entirely unremarkable, except for a reduced estimated glomerular filtration rate of 58 ml / min / 1.73 m². The rugby club had then informed the player of the need to attend his GP with the result, who referred the patient for urgent renal review.

The patient reports feeling very well in himself, but very concerned about the possibility that he had developed renal failure. The patient had never previously been aware of any problems involving his kidneys and his only previous medical concern was a successful emergency operation for testicular torsion 10 years previously. He denied any history of diabetes, hypertension, connective tissue disease, renal calculi or prostatic symptoms. There was no family history of kidney disease. The patient took no regular medications, and occasionally took over-the-counter ibuprofen if he suffered a sports injury, but not at other times. Due to his career, the patient was extremely physically active and regularly attended the gym for strength training.

On examination, the patient appeared to be generally very healthy, with a highly developed athletic physique. Cardiovascular, respiratory and abdominal examination was entirely unremarkable. Please see below for investigations arranged around 3 months after the initial blood tests, as part of the patient's referral to the renal clinic.

Haemoglobin	169 g / dL
Mean cell volume	87 fl
White cell count	9.5 x 10 ⁹ / microlitre
Platelets	243 x 10 ⁹ / microlitre
Urea	7.0 mmol / L
Creatinine	126 micromol / L
eGFR	56 ml / min / 1.73 m ²
Sodium	142 mmol / L
Potassium	4.3 mmol / L
Urinalysis	no abnormality detected

Urine microscopy	no abnormality detected
Albumin:creatinine ratio	1.9 mg / mmol (reference < 3)

What is the appropriate next investigation?

	Ultrasound renal tract
	Renal biopsy
	Genetic testing for PKD-1, PKD-2 and PKD-3 genes
	Serum cystatin-C
	Anti-neutrophil cytoplasmic antibodies

□ Question 94 of 144

A 57-year-old man is admitted with general lethargy. He is currently being treated for bladder cancer, which has been complicated by paraneoplastic Guillain-Barré syndrome. Focussed examination is largely unremarkable. His bloods are printed off by the FY1:

Na+	139 mmol/l
K+	4.1 mmol/l
Urea	20.1 mmol/l (Baseline 4.2 mmol/l)
Creatinine	526 µmol/l (Baseline 86 µmol/l)
CRP	50 mg/l

An urgent KUB ultrasound is arranged, producing the following conclusion:

Severe bilateral hydronephrosis.

His urinalysis is as follows:

Nitrites	+ve
Leucocytes	3+
Blood	2+
Protein	1+

What is the most likely cause of his hydronephrosis?

	Urinary tract infection
	Ureteric blood clot

	Renal tract calculi
	Malignant infiltration of the ureters
	Retroperitoneal fibrosis

□ Question 95 of 144

A 48-year-old gentleman with chronic kidney disease secondary to adult polycystic kidney disease presents with a three-month history of increasing lethargy and fatigue. He reports feeling 'tired all the time' and some mild shortness of breath on climbing stairs. He denies any feelings of light headedness and has walked from the car park to the clinic without any difficulty. On examination he is pale. He has bilateral ballotable kidneys and fullness in the flanks. In his left arm, he has a maturing arterio-venous fistula that has not yet been used.

Bloods show:

Hb	80 g/l
Platelets	$125 \times 10^9/l$
WBC	$4.4 \times 10^9/l$

Na ⁺	135 mmol/l
K ⁺	4.8 mmol/l
Urea	12.2 mmol/l
Creatinine	265 μ mol/l
eGFR	15ml/min

Ferritin	102ng/ml
Transferrin saturation	23%

What is the best strategy for managing this patients' anaemia?

	Transfusion of two units of packed red blood cells immediately.
	Measurement of serum erythropoietin levels before any treatment.

	Commencement of erythropoiesis stimulating agents (ESA) aiming for a haemoglobin of 100-120 g/dL
	Commencement of erythropoiesis stimulating agents with a target haemoglobin of 120-140 g/dL
	Trial of oral steroids

□ Question 97 of 144

A 22-year-old male was admitted with severe abdominal pain. The pain was in his left flank area going down into his groin. It was constant and he was not able to lie still with the pain. With the pain he felt nauseated. He did not notice any urinary symptoms. He had a similar episode six months ago which resolved with conservative management. He stated since the episode he increased his fluid intake and instituted a trial of dietary change. He was otherwise fit and well, except for a past medical history of asthma for which he used Clenil modulite 200mcg BD and salmeterol 100mcg BD. He smoked 20 cigarettes per day and consumed 20 units of alcohol per week mainly at the weekends.

On examination, he was in obvious discomfort and restless. His blood pressure was 118/72 mmHg, his heart rate was 88 and his temperature was 36.9 degrees celsius. Examination of the cardiovascular system revealed the presence of normal heart sounds with warm well perfused peripheries. Other than tachypnoea, examination of his respiratory system was unremarkable. Examination of his gastrointestinal system revealed the presence of left renal angle tenderness but otherwise a soft non-tender abdomen with no evidence of guarding or rigidity. Examination of his neurological system was unremarkable.

A number of investigations were performed:

Na ⁺	142 mmol/l
K ⁺	4.0 mmol/l
Urea	4.2 mmol/l
Creatinine	77 µmol/l
CRP	12 mg/l
Adjusted calcium	2.40 mmol/l

Urinalysis: blood +++, nil else

KUB x-ray: single solitary area of calcification within left kidney

The patient was treated conservatively with an intravenous fluid infusion, non-steroidal anti-inflammatory drugs and opioid analgesia and within 48 hours recovered fully.

He was subsequently seen in the renal clinic where he underwent a number of investigations:

Urea and electrolytes	normal
Urate	0.39 (NR 0.12-0.42 mmol/l)
Vitamin D	62 (NR 30 100 ng/ml)
Parathyroid hormone 48	(NR 11-54 pg/ml)
Urine 24 hr collection	Calcium 525 (NR 25 - 300mg/24hrs) Oxalate 21 (NR 7 - 44 mg/24hrs) Citrate 588 (NR 320 1240mg/24hrs) Sodium 137 (NR 40 220mg/24hrs)

Which therapeutic option will most likely be of benefit in the prevention of future episodes?

	Calcium carbonate
	Bendroflumethiazide
	Allopurinol
	Captopril
	Furosemide

Question 98 of 144

A 41-year-old lady was admitted feeling generally unwell with a headache, generalised aches and pains, lethargy and fevers. She had a previous medical history of type one diabetes and end-stage renal failure. She had undergone a simultaneous pancreas-kidney transplant ten months prior to admission with good graft function. Four months previously she had been admitted with neutropaenia which had led to the early cessation of her valganciclovir and a reduction in her immunosuppression. Her medications comprised of tacrolimus, prednisolone, mycophenolate and aspirin. On examination, she appeared pale, lethargic and unwell. She had a mid-line laparotomy scar with a palpable renal transplant in the left iliac fossa. Her temperature was 39.4 degrees Celsius, her pulse was 115 beats per minute and regular, her blood pressure was 102/59 mmHg, her respiratory rate was 22 breaths per minute and her oxygen saturations were 95% on room air.

Investigations:

Haemoglobin	108g/L
White cell count	$9.2 \times 10^9 /L$
Platelet Count	$347 \times 10^9 /L$
Neutrophil Count	$7.6 \times 10^9 /L$
Lymphocyte count	$0.5 \times 10^9 /L$

Serum sodium	129mmol/L
Serum potassium	5.4mmol/L
Serum urea	7.4mmol/L
Serum creatinine	174micromol/L
Albumin	32g/L
Alkaline phosphatase	204 IU/L
Alanine transaminase	46 IU/L
CRP	101mg/L

Chest X-ray: clear lung fields

What is the most likely diagnosis?

	Urinary tract infection
	Hepatitis C infection
	Cytomegalovirus infection
	Upper respiratory tract infection
	BK virus infection

□ Question 99 of 144

A 64-year-old woman is seen in the low clearance renal clinic. She has a history of chronic kidney disease stage IV secondary to previous bilateral ureteric injury during hysterectomy with non-resolving acute kidney injury.

She is currently feeling well aside from some mild ankle swelling. She is currently taking losartan, alfacalcidol, calcium, cholecalciferol and sodium bicarbonate.

On examination she has a blood pressure of 175/91 mmHg and a heart rate of 92 beats per minute. She has normal heart sounds and her chest is clear. Her JVP is visible at 4cm and she has pitting oedema to the ankles.

Her blood tests are as follows:

Hb	121 g/l	Na ⁺	137 mmol/l
Platelets	241 * 10 ⁹ /l	K ⁺	5 mmol/l
WBC	5 * 10 ⁹ /l	Urea	18 mmol/l
Neuts	2 * 10 ⁹ /l	Creatinine	387 µmol/l
Ca ²⁺	2.24 mmol/l	Phos	1.1 mmol/l

Which medication should be added to control her hypertension?

	Amlodipine
	Bendroflumethiazide
	Furosemide
	Metolazone
	Ramipril

□ Question 103 of 144

An 18-year-old man presents to the Emergency Department with a 3-hour history of severe left flank pain radiating to the groin. The pain is constant but waxes and wanes. He tells you he has had this pain before and that it is due to 'kidney stones'.

His electronic hospital record documents three previous admissions with ureteric calculi; the most recent episode requiring intervention with ureteric stents and lithotripsy. He takes no regular medications but consumes 3 litres of water per day on the advice of the urologists.

On examination, he is restless and pacing. He is afebrile, his pulse is 93bpm and his blood pressure is 148/79mmHg. His abdomen is soft but there is percussion tenderness over the left costovertebral angle. A plain abdominal film shows a semi-opaque, left proximal ureteric stone with a 'ground glass' appearance.

His 24-hour urine results are as follows:

Calcium	3.1 mmol/day (2.5 - 7.5)
Oxalate	0.28 mmol/day (0.11 - 0.46)
Phosphate	17.4mmol/day (15 - 20)
Urate	1.8mmol/day (1.5 - 4.5)
Cystine	1.9mmol/day (<0.13)
pH	7.5

Given the likely diagnosis, what is the most appropriate treatment?

	Allopurinol
	Potassium citrate
	Sodium bicarbonate

	D-penicillamine
	Bendroflumethiazide

Dashboard

□ Question 104 of 144

□ □

A 32-year-old woman with a history of systemic lupus erythematosus and stable joint disease currently managed with hydroxychloroquine comes to the nephrology clinic. She complains of worsening peripheral oedema. Examination reveals a blood pressure of 159/88 mmHg, his pulse is 78 beats per minute and regular. There is pitting oedema of both lower limbs.

investigations

Na ⁺	141 mmol/l
K ⁺	5.1 mmol/l
Urea	8.1 mmol/l
Creatinine	159 µmol/l
Creatinine one month earlier	132 µmol/l
Urinary protein	5 g/24hrs

Which of the following is the most appropriate intervention with respect to long-term renal outcomes?

	Cyclophosphamide
	Methotrexate
	Methylprednisolone
	Mycophenolate
	Rituximab

Overall score: **0%**

Question 105 of 144

□ □

A 32-year-old female patient presents with a generalised maculopapular rash accompanied with fever and lower back pain. She has also noted swelling in both her legs. She had been seen by her GP three weeks ago and was given amoxicillin for a chest infection. A urinalysis was carried out and the result is shown below -

Urinalysis

Blood +++

White cells +++ (eosinophils+++)

No organisms seen

Glucose -

Nitrates -

Blood tests:

Hb	10.6 g/dl
MCV	86 fl
Platelets	$390 \times 10^9/l$
WBC	$9.2 \times 10^9/l$

Na ⁺	136 mmol/l
K ⁺	4.2 mmol/l
Urea	12.4 mmol/l
Creatinine	135 μ mol/l

What is the most likely diagnosis?

	Minimal change nephropathy

	Membranous glomerulonephritis
	Acute interstitial nephritis
	Drug-induced lupus
	Acute proliferative glomerulonephritis

□ Question 109 of 144

A 21-year-old male with end stage renal failure who had undergone a cadaveric renal transplant 8 weeks previously presented with haematuria and a decline in his graft function from a serum creatinine of 110 $\mu\text{mol/L}$ to 320 $\mu\text{mol/L}$. He developed renal failure and sensorineural deafness in childhood. He was compliant with his current medications which included prednisolone, tacrolimus and cyclophosphamide. Three of his maternal uncles had developed renal failure in their teenage years.

On examination, he appeared well but pale with a scar in the left iliac fossa and a palpable, tender renal graft. His temperature was 37.2 degrees Celsius, his pulse was 85 beats per minute and regular, his blood pressure was 112/75 mmHg, his respiratory rate was 18 breaths per minute and his oxygen saturations were 97% on room air.

Investigations:

Urine dip: blood+++, protein++

Haemoglobin	95 g/L
White cell count	$7.7 \times 10^9/\text{L}$
Platelet Count	$181 \times 10^9/\text{L}$
INR	0.9
Serum sodium	141mmol/L
Serum potassium	5.1mmol/L
Serum urea	20.4mmol/L
Serum creatinine	320micromol/L
CRP	24 mg/L

Renal transplant ultrasound scan: The renal transplant lies in the left iliac fossa. It is normal in size with increased cortical echo texture. There is no hydronephrosis. Doppler studies demonstrate good arterial and venous flow.

What is the most likely reason for the decline in graft function?

	Cytomegalovirus infection
	Urinary tract infection
	Anti-glomerular basement membrane antibodies
	Dehydration
	Urinary calculi

Dashboard

□ Question 110 of 144

A 65-year-old man is admitted with central chest pain that has been ongoing for two hours. It radiates to the left arm and is associated with nausea and vomiting. He has a past medical history of hypertension and diabetes which is diet controlled. He takes amlodipine and atorvastatin.

On examination his blood pressure is 147/89 mmHg and his heart rate is 110 beats per minute. His saturations are 96% on room air and he is afebrile. His cardiovascular and respiratory examinations are unremarkable.

An ECG shows T wave inversion in leads I, V4, V5 and V6.

Blood tests are as follows:

Hb	131 g/l	Na ⁺	136 mmol/l
Platelets	430 * 10 ⁹ /l	K ⁺	4 mmol/l
WBC	8 * 10 ⁹ /l	Urea	4 mmol/l
Neuts	6 * 10 ⁹ /l	Creatinine	84 µmol/l
Lymphs	1 * 10 ⁹ /l	CRP	41 mg/l
Eosin	0.3 * 10 ⁹ /l	Trop	130 ng/l

He is diagnosed with non-ST elevation myocardial infarction and commenced on aspirin, clopidogrel and low molecular weight heparin. His pain settles with morphine and glyceryl trinitrate spray within an hour. The following day he is commenced on ramipril and bisoprolol. 3 days later he undergoes an uncomplicated angiogram with stenting of the left circumflex artery.

On systems reviews prior to discharge he comments that he has noticed a rash on his legs and has not been passing much urine despite drinking plenty of water. On examination he has a bluish lacey discolouration over his legs. He has no palpable bladder.

Repeat bloods are as follows:

Hb	12.1 g/l	Na ⁺	137 mmol/l
----	----------	-----------------	------------

Platelets	560 * 10 ⁹ /l	K ⁺	5 mmol/l
WBC	10 * 10 ⁹ /l	Urea	12 mmol/l
Neuts	7 * 10 ⁹ /l	Creatinine	184 µmol/l
Lymphs	1.2 * 10 ⁹ /l	CRP	60 mg/l
Eosin	1.5 * 10 ⁹ /l		

What is the most likely cause of his symptoms and deranged blood tests?

	Cholesterol embolism
	Contrast nephropathy
	Endocarditis
	Hypovolaemia during NSTEMI
	Newly started ACE inhibitor

□ □

A 51 year-old man presents with a twelve hour history of generalised abdominal pain, nausea and vomiting. The abdominal pain has been increasing in severity to a 6/10 on the pain scale and there is evidence of guarding. The patient is currently on peritoneal dialysis for end-stage renal failure and he has noticed cloudy peritoneal bags over the last six hours. He is on ramipril, alfacalcidol, erythropoietin and simvastatin and is allergic to penicillin. His observations are all stable and peritoneal dialysis fluid has been sent off for microscopy, culture and sensitivity.

What is the next most appropriate management of this patient?

<input type="checkbox"/>	Give IV co-amoxiclav
<input type="checkbox"/>	Arrange immediate removal of catheter
<input type="checkbox"/>	Swab catheter site and give erythromycin
<input type="checkbox"/>	Give intra-peritoneal vancomycin and gentamicin
<input type="checkbox"/>	Perform a sepsis screen and await peritoneal dialysis fluid microscopy result

□ Question 113 of 144

A 72-year-old man presents to the Emergency Department with worsening shortness of breath over the last three days. He denies any history of angina or orthopnoea and denies any recent fever. He has a slight cough over the last week and yesterday noted a small amount of blood in his otherwise clear sputum. His past medical history includes type two diabetes mellitus for which he takes metformin and gliclazide. On a more detailed systems review, he admits to feeling generally run down over the last week and has noticed he hasn't been passing much urine in the last two days.

On examination, he is breathless at rest with a respiratory rate of 26 breaths/min, oxygen saturations of 88% on air and a few scattered crepitations on auscultation. His heart rate is 95 beats/min, his blood pressure 169/102 mmHg and his capillary refill time is less than three seconds. His heart sounds are normal, there is no significant peripheral oedema and his mucous membranes are moist. His abdomen is soft to palpation and there is no organomegaly. After urinary catheterization only a small amount of urine is passed and the nurse reports it only showed protein and blood. A chest x-ray reveals widespread patchy infiltrates.

Hb	105 g/l
Platelets	$490 \times 10^9/l$
WBC	$8.5 \times 10^9/l$
Na ⁺	139 mmol/l
K ⁺	5.1 mmol/l
Urea	31.5 mmol/l
Creatinine	894 μ mol/l

What is the most appropriate treatment?

	Plasmapheresis
	Crystalloid infusion
	Haemofiltration

	High dose steroids
	Dialysis

□ Question 115 of 144

□ □

A 45-year-old man presents to the Emergency Department complaining of loin pain and passing blood in his urine. This is not the first time he has had similar symptoms but they are generally not as severe. The pain is concentrated around the left loin region and is described as 'dull' and 6/10 in terms of severity. He is generally fit and well but is currently awaiting ambulatory blood pressure monitoring by his GP as he had a borderline blood pressure at a recent medical.

He has recently been on holiday in Greece. He works as a car mechanic and drinks around 30 units of alcohol per week.

Blood tests in the Emergency Department show the following:

Hb	13.9 g/dl	Na ⁺	141 mmol/l
Platelets	286 * 10 ⁹ /l	K ⁺	4.8 mmol/l
WBC	6.9 * 10 ⁹ /l	Urea	6.9 mmol/l
		Creatinine	109 µmol/l
		CRP	14 mg/l

A presumed diagnosis of renal colic is made and a CT requested:

□ Question 115 of 144

□ □

A 45-year-old man presents to the Emergency Department complaining of loin pain and passing blood in his urine. This is not the first time he has had similar symptoms but they are generally not as severe. The pain is concentrated around the left loin region and is described as 'dull' and 6/10 in terms of severity. He is generally fit and well but is currently awaiting ambulatory blood pressure monitoring by his GP as he had a borderline blood pressure at a recent medical.

He has recently been on holiday in Greece. He works as a car mechanic and drinks around 30 units of alcohol per week.

Blood tests in the Emergency Department show the following:

Hb	13.9 g/dl	Na ⁺	141 mmol/l
Platelets	286 * 10 ⁹ /l	K ⁺	4.8 mmol/l
WBC	6.9 * 10 ⁹ /l	Urea	6.9 mmol/l
		Creatinine	109 µmol/l
		CRP	14 mg/l

A presumed diagnosis of renal colic is made and a CT requested:

© Image used on license from Radiopaedia

What is the most likely underlying diagnosis?

	Metastatic renal cell cancer
	Pseudomyxoma peritonei
	Autosomal dominant polycystic kidney disease
	Hydatid disease
	Medullary cystic disease

Question 116 of 144

□ □

A 42-year-old woman of Afro-Caribbean ethnicity is admitted to hospital after a two-week history of non-specific fatigue and worsening lower limb swelling. She was diagnosed with systemic lupus erythematosus 6 years ago and over the 6 months, her creatinine has been slowly rising from 120 $\mu\text{mol/l}$ to 260 $\mu\text{mol/l}$.

On examination, her blood pressure is 180/118 mmHg, she has significant swelling of ankles and feet, with periorbital oedema. A urine dip demonstrated 4+ protein and a 24 hour urine collection collected 4.6g protein. She undergoes a renal biopsy under the renal physicians, demonstrating membranous lupus nephritis. In addition to angiotensin-converting enzyme inhibitors, statins and anti-hypertensives, what is the most appropriate immediate treatment?

	Monitor
	PO prednisolone alone
	IV methylprednisolone alone
	IV methylprednisolone and IV cyclophosphamide
	Plasmaphoresis

□ Question 117 of 144

A 30-year-old woman with a background of systemic lupus erythematosus presents to the emergency department with fatigue and poor urine output.

On examination, she is jaundiced, with a petechial rash affecting her lower limbs which is non-tender to palpation. She is afebrile, mildly tachycardiac with a heart rate of 95/min and is normotensive.

Bloods:

Hb	50 g/l	Na ⁺	135 mmol/l
Platelets	30 × 10 ⁹ /l	K ⁺	4.9 mmol/l
WBC	11 × 10 ⁹ /l	Urea	6 mmol/l
Neuts	6 × 10 ⁹ /l	Creatinine	300 µmol/l
Lymphs	3 × 10 ⁹ /l	CRP	25 mg/l
Eosin	0 × 10 ⁹ /l		

What is the most appropriate definitive management?

	Transfusion of packed red cells
	Intravenous fluids
	Rituximab
	Pulsed methylprednisolone
	Plasma exchange

Overall score: **0%**

□ Question 118 of 144

□ □

You review a 65-year-old gentleman in the renal outpatients clinic with diabetic nephropathy. He has opted for hospital haemodialysis and is awaiting fistula creation. He complains of tiredness and poor exercise tolerance. He is clinically euvolaemic. His blood results are as follows:

Na ⁺	134 mmol/l
K ⁺	5.6 mmol/l
HCO ₃ ⁻	21 mmol/l
Urea	29 mmol/l
Creatinine	480 µmol/l
Hb	89 g/l
MCV	81 fL
Ferritin	500 ng/mL

What would be the best management of his anaemia?

	Ferric carboxymaltose (IV iron)
	Oral ferrous sulphate
	Erythropoietin (intravenous)
	Erythropoietin (subcutaneous)
	Regular blood transfusion

Overall score: **0%**

□ Question 119 of 144

□ □

A 62-year-old woman with a history of type 1 diabetes and end stage renal failure comes to the renal clinic for review. Over the past few months she has been feeling increasingly lethargic with proximal muscle pains and weakness. She is managed with a basal bolus insulin regime, Examination reveals a blood pressure of 155/82 mmHg, pulse is 70 beats per minute and regular. Chest is clear, there is no ankle swelling. Abdomen is soft and non-tender. You confirm proximal muscle weakness.

Investigations

Hb	101 g/l	Na ⁺	137 mmol/l	Bilirubin	11 µmol/l
Platelets	95 * 10 ⁹ /l	K ⁺	3.7 mmol/l	ALP	185 u/l
WBC	8.4 * 10 ⁹ /l	Urea	13.2 mmol/l	ALT	23 u/l
Neuts	5.1 * 10 ⁹ /l	Creatinine	382 µmol/l	γGT	57 u/l
Lymphs	2.1 * 10 ⁹ /l	Ca ⁺⁺	2.1 mmol/l	Albumin	30 g/l

You suspect that she has secondary hyperparathyroidism. At what level of PTH would you begin supplementation with calcium and vitamin D?

	In the normal range
	Just above the normal range
	Twice the normal range
	Three times the normal range
	Four times the normal range

Overall score: **0%**

Question 120 of 144

□ □

A 32 year old gentleman presented to your acute medical unit with right flank pain. The pain started 2 weeks ago and has been constant. He has tried paracetamol tablets but this has not relieved the pain. He denies any dysuria and is otherwise fit and well. He is a smoker and tells you that his sister recently died from a subarachnoid haemorrhage, which was caused by a berry aneurysm.

He is tachycardic at 110 bpm but other observations are normal. Urine dipstick has 2+ blood, nil else. His blood tests reveal a Sodium 141 mmol/l, Potassium 4.6 mmol/l, Urea 3.6 mmol/l, Creatinine 84µmol/l, CRP 34mg/l. His FBC is normal.

What is the most likely diagnosis?

	Renal stone
	Pyelonephritis
	Renal cell carcinoma
	Polycystic kidney disease
	Wilms' tumour

Question 122 of 144

A 24-year-old student attends hospital with visible haematuria. He has been unwell for 2 days with a sore throat and fevers. He has been prescribed amoxicillin by his GP and these symptoms are improving. He is concerned by the sudden appearance of haematuria. He has no dysuria or frequency. He is normally well and takes no regular medications. He has not noticed visible haematuria before now. He smokes 10 cigarettes/day.

On your assessment, his observations are as follows:

- Temperature 36.2
- Respiratory rate 18/min
- Saturations 97% on air
- Heart rate 76 bpm
- Blood pressure 130/80 mmHg

Throat examination reveals pharyngeal erythema.

Bloods are as follows:

Hb	132 g/l
Platelets	235 * 10 ⁹ /l
WBC	14.0 * 10 ⁹ /l
Na ⁺	138 mmol/l
K ⁺	4.0 mmol/l
Urea	3.2 mmol/l
Creatinine	62 µmol/l
CRP	85 mg/l

Urine dipstick shows 4+ blood.

What is the best management?

	Admit under renal team for renal biopsy
	Admit under urology for urgent investigation of haematuria
	Discharge and refer to urology for investigation of haematuria
	Discharge with routine renal outpatient referral
	Discharge with no follow up

□ Question 123 of 144

□ □

A 47-year-old male is referred by his GP in the urgent care centre to the medical team for review. The patient describes 5 months of non-specific symptoms, describing fatigue and malaise with no focal symptoms. He reports that his 'urine looks a bit weird' and a sample reveals frothy urine. A urine dip reveals 4+ protein 4+ blood no leucocytes or nitrites. His resting blood pressure is 190/120 mmHg. On examination, you note bilateral periorbital oedema, a right varicocele and prominent abdominal veins. You also note significant swelling around both eyes. His past medical history includes intravenous drug use, one previous admission for cellulitis around a groin injection site, positive hepatitis B and atopic dermatitis. He denies drug use over the past 2 months and denies any recent infections.

His first serum results are as follows:

Hb	105 g/l
Platelets	$426 \times 10^9/l$
WBC	$11.2 \times 10^9/l$

Na ⁺	138 mmol/l
K ⁺	4.3 mmol/l
Urea	16 mmol/l
Creatinine	230 μ mol/l
Albumin	19 g/l
CRP	16 mg/l

An urgent ultrasound of his renal tract reveals a right renal vein thrombus.

What is the most likely underlying diagnosis?

	Minimal change disease
	Membranous glomerulonephritis

	Primary focal segmental glomerulosclerosis
	Right renal vein thrombosis
	Goodpasture's syndrome

Dashboard

Overall score: 0%

□ □

A 24-year-old man comes to the Emergency department complaining of macroscopic haematuria. He has also been suffering from a sore throat and cough for the past 48hrs. He tells you that he had a previous episode of haematuria after a respiratory tract infection some 4 years earlier. On this occasion he has been prescribed co-amoxiclav by his GP and feels that his symptoms are improving. On examination his blood pressure is 122/80 mmHg, pulse is 67 and regular. he is afebrile. Auscultation of the chest reveals minor crackles at the left base, and he has obvious pharyngitis.

Relevant investigations:

Creatinine	85 mmol/l
Urine	blood + + +

Which of the following is the most appropriate intervention?

	Valsartan
	Observation only
	Prednisolone
	Stop co-amoxiclav
	Ramipril

Question 126 of 144

□ □

A 59-year-old gentleman is admitted to hospital with lower abdominal pain. He has a past medical history includes Parkinson's disease, psoriasis and high cholesterol. Current medications include methotrexate 10mg once weekly, bromocriptine 2.5mg BD, atorvastatin 20mg ON, levodopa 200mg TDS and entacapone 200mg OD.

Observations on admission are as follows: heart rate 102 beats per minute, blood pressure 125/62 mmHg, respiratory rate 18/min, oxygen saturations 97% (room air), temperature 37.2°C. On examination, there is bilateral loin tenderness, with no evidence of peritonism. Bowel sounds are active. Urine dipstick confirms blood 2+ with no evidence of nitrites or leucocytes. An abdominal x-ray is unremarkable.

Which medication is likely to be implicated with the underlying diagnosis?

	Bromocriptine
	Entacapone
	Methotrexate
	Atorvastatin
	Levodopa

Question 127 of 144

□ □

You are the medical doctor on an acute medical admissions unit. A 42-year old gentleman with type 1 diabetes and Alport's syndrome presents with an acute kidney injury following a renal transplant 2 weeks ago from his brother (still alive). He is on immunosuppressive therapy (tacrolimus and mycophenolate mofetil) and otherwise feels well. Examination is normal but his urine dipstick has 3+ blood and protein.

His blood tests are as follows:

Na ⁺	141 mmol/l
K ⁺	4.7 mmol/l
Urea	18.6 mmol/l
Creatinine	288 µmol/l (baseline 80 µmol/l)
eGFR	34 ml/min (baseline 82 ml/min)

What is the most likely cause of his presentation?

	Acute graft rejection
	Accelerated graft rejection
	Renal vein thrombosis
	CMV infection
	Goodpasture's syndrome

Dashboard

A 36 year male presents with sudden onset, sharp, right sided chest pain and a 4 month history of increasing leg swelling, weight gain and abdominal distension. He has no past medical history of note. On examination he is tachycardic at 105/min with otherwise normal observations. Cardiovascular and respiratory examinations are normal; there is shifting dullness on examination of the abdomen with no masses palpable. There is also bilateral pitting oedema to the groins. Electrocardiogram shows sinus tachycardia. Urine dip shows 3+ protein nil else. Chest X-ray is unremarkable. Blood tests show the following:

Hb	137 g/l	Na ⁺	141 mmol/l	Bilirubin	12 µmol/l
Platelets	275 * 10 ⁹ /l	K ⁺	4.4 mmol/l	ALP	89 u/l
WBC	9.2 * 10 ⁹ /l	Urea	4.3 mmol/l	ALT	33 u/l
Neuts	7.3 * 10 ⁹ /l	Creatinine	86 µmol/l	γGT	47 u/l
Lymphs	1.4 * 10 ⁹ /l	Albumin	20 g/l		

What is the most likely cause of his chest pain?

	Pulmonary embolism
	Acute coronary syndrome
	Aortic dissection
	Pneumothorax
	Musculoskeletal chest pain

□ Question 131 of 144

A 40-year-old man with end-stage chronic kidney disease is seen in the Emergency Department with a swollen right arm. He has dialysis 3 times per week through a fistula in the right arm but dialysis has been painful on the last two sessions and he has had to stop 30 minutes early on both occasions. He does not complain of swelling elsewhere. He has no shortness of breath and no fevers. His past medical history is of reflux nephropathy and hypertension. He has no history of thromboembolism. He has been on dialysis through this fistula for 2 years and the swelling has been developing over the last 2 weeks.

On examination his heart rate is 83 beats per minute, blood pressure 157/94 mmHg, temperature 36.8 °C and oxygen saturations 98% on air. He has a diffusely swollen right arm with no erythema. His fistula site is clean with recent evidence of needle marks and no discharge. There is a palpable thrill and an audible bruit. His chest is clear and JVP is 2cm. There is no oedema of the contralateral arm and mild oedema of both feet.

Chest x-ray shows mild chronic cardiomegaly with clear lung fields.

Blood results are as follows:

Hb	105 g/l	Na ⁺	135 mmol/l
Platelets	170 * 10 ⁹ /l	K ⁺	5.1 mmol/l
WBC	9 * 10 ⁹ /l	Urea	21 mmol/l
Neuts	5.5 * 10 ⁹ /l	Creatinine	753 µmol/l
Lymphs	2.2 * 10 ⁹ /l	CRP	18 mg/l

What is the most likely likely diagnosis?

	Cellulitis
	Deep vein thrombosis
	Fistula stenosis

	Post-surgical lymphoedema
	Superior vena cava obstruction

Dashboard

Overall score: **0%**

□ Question 133 of 144

A 40-year-old woman is brought to the GP by her husband due to her recent onset of lethargy and confusion. For the past few days she has been complaining of intense thirst, craving for ice water and increased urination, particularly at night. Her medications include lithium and olanzapine for bipolar disorder and lansoprazole for acid reflux.

Her temperature is 37.2°C, blood pressure is 83/59 mmHg, pulse is 122/min and respiratory rate is 15/min. Physical examination shows a disoriented woman with reduced skin turgor and dry mucous membranes.

Laboratory results are as follows:

Na ⁺	156 mmol/l
K ⁺	4.1 mmol/l
Urea	9.6 mmol/l
Creatinine	141 µmol/l
Chloride	110 mmol/l
Bicarbonate	24 mmol/l
Serum glucose	9.9 mmol/l
Serum osmolality	328 mOsm/kg
Urine osmolality	180 mOsm/kg
Serum lithium	pending

Which of the following is the most appropriate next step in management of this patient?

	Haemodialysis
	I.V. 0.45% normal saline
	I.V. 0.9% normal saline

	I.V. 5% dextrose
	Water deprivation test

□ Question 134 of 144

A 22-year-old female presents to the Emergency Department with blood in her urine. She produces a sample, demonstrates painless rose coloured macroscopic haematuria. She reports no past medical history except a single episode of a urinary tract infection about 5 years ago and a recent 'cough and sore throat' that had got better two weeks ago. Her family has no history of bladder or kidney problems except her mother having 'shockwave treatment to her kidney tubes a few years ago'. She is sexually active with a regular partner, her last menstrual period was 3 weeks ago. On examination, her abdomen is soft and non-tender with no organomegaly. Urine dip demonstrates 4+ blood, 1+ protein. Her blood tests are as follows:

Hb	125 g/l
Platelets	259 * 10 ⁹ /l
WBC	12.1 * 10 ⁹ /l

Na ⁺	139 mmol/l
K ⁺	4.8 mmol/l
Urea	5.6 mmol/l
Creatinine	72 µmol/l
CRP	3 mg/l

Beta HCG	negative
HIV	negative
CMV IgG	positive
CMV IgM	negative
EBV IgG	positive
Anti-streptolysin titre	positive

Chest radiography is unremarkable. Ultrasound of her renal tract shows normal sized kidneys with no hydronephrosis.

What is the diagnosis?

	IgA nephropathy
	Diffuse proliferative glomerulonephritis
	Minimal change disease
	Membranoproliferative glomerulonephritis
	Ureteric calculi

Dashboard

Overall score: 0%

□ Question 136 of 144

A 65 year old man with a history of ischemic heart disease, hypertension, and type 2 diabetes mellitus presents with a 10 week history of vague abdominal pain, fatigue, and lately finding it difficult to walk for a long distance because of pain in his legs. He is a heavy smoker for 30 years. His blood pressure is controlled on amlodipine, and his blood sugar is well controlled on glimepiride. He occasionally uses sildenafil for his erectile dysfunction.

On examination his blood pressure 130/80 mmHg, pulse rate 76 beats per minute. His peripheral pulses feels weak on palpation and bilateral lower limb oedema is noted.

The following investigations were ordered:

Na+	140 mmol/l
K+	4 mmol/l
Urea	13 mmol/l
Creatinine	120 mmol/l
ESR	60 mm/hr
Random blood glucose	7 mmol/l
Urine dipstick	Protein +
Hb	12 g/dl
platelets	$200 \times 10^9/l$
WBC	$6 \times 10^9/l$
MCV	80 fl
MCH	0.4 fmol/cell
MCHC	20 mmol/l
ANA	positive

What is the most likely cause for the deterioration in his renal function?

	Chronic interstitial nephritis (CIN)
	Renal artery stenosis (RAS)
	Renal stone
	Takayaso vasculitis
	Retroperitoneal fibrosis

Dashboard

Overall score: 0%

□ □

A 42-year-old man attends for follow-up in renal clinic. The patient has been under surveillance for autosomal dominant polycystic kidney disease for the previous 10 years. The patient is currently asymptomatic but concerned about an ongoing decline in his renal function as monitored by his general practitioner. He has no other past medical history. The patient took ramipril 5 mg daily and had no allergies.

Clinical examination demonstrated bilateral palpable kidneys with a euvolaemic fluid status. Blood pressure in clinic was documented as 105 / 70 mmHg.

Please see below for serial renal function and ultrasound results over the period of follow-up.

Date	Estimated globular filtration rate mL / min / 1.73 m3
10 years previous	72
8 years previous	68
5 years previous	62

□ Question 138 of 144

A 45-year-old man is referred to ambulatory care by his GP due to bilateral leg swelling and a subsequent urine dipstick showing proteinuria. He is otherwise fit with no past medical history and works as a school caretaker. He had a throat infection and joint pain two weeks ago which was treated with penicillin by his GP. This has been associated with some arthralgia and myalgia. He was beginning to feel better when the leg swelling started.

On examination he has bilateral pitting oedema to the knees. His JVP is not raised and his heart sounds are normal. His chest is clear and his throat does not appear infected currently. His abdomen is soft with no masses. He has no rash or joint swelling.

His urine dipstick shows 3+ protein.

His blood tests are as follows:

Hb	118 g/l	Na ⁺	131 mmol/l
Platelets	190 * 10 ⁹ /l	K ⁺	4.7 mmol/l
WBC	8 * 10 ⁹ /l	Urea	12 mmol/l
Neuts	5.5 * 10 ⁹ /l	Creatinine	131 µmol/l
Albumin	29g/l	CRP	25 mg/l

He is admitted and further testing reveals the following:

US kidneys - Normal size kidneys with no evidence of obstruction in the renal system.

Antistreptolysin O titre	104 IU (negative)
Complement C3 & C4	Mildly raised
Antiphospholipase A2 antibody	Positive
Double-stranded DNA	Normal
Anti-neutrophil cytoplasmic antibody	Negative

He has a renal biopsy which shows thickened basement membranes with subepithelial deposits on electron microscopy.

What is the most likely cause of his membranous glomerulonephritis?

	Anti-phospholipid syndrome
	Idiopathic
	Lupus nephritis
	Penicillin
	Post-infectious

□ Question 139 of 144

You are seeing a 78 year old man in renal outpatient clinic with known CKD4. He is feeling much better than he did last time he saw you in clinic and only occasionally feels slightly tired, a problem which is only occasionally limiting. You saw him three months ago with similar problems and had started him on iron replacement therapy (ferrous fumarate 210mg three times daily). His bloods at clinic three months ago and today are shown below:

Three months ago:

Hb	77 g/l
Platelets	$178 \times 10^9/l$
WBC	$3.2 \times 10^9/l$
MCV	71 fl
Ferritin	78 ng/ml
Transferrin saturations	12%
B12	451 pg/ml
Folate	4.8 nmol/nl
TSH	2.1 mIU/L

Today:

Hb	101 g/l
Platelets	$172 \times 10^9/l$
WBC	$4.5 \times 10^9/l$
MCV	78 fl
Ferritin	621 ng/ml
Transferrin saturations	21%

B12	721 pg/ml
Folate	3.8 nmol/nl
TSH	2 mIU/L

What would you do next?

	Increase his ferrous fumarate to 210mg four times daily
	Decrease his ferrous fumarate to 210mg twice daily
	Do not change any of his medications
	Transfuse him 1 unit of packed red cells
	Start an ESA (erythrocyte colony stimulating agent)

Dashboard

Overall score: 0%

□ Question 140 of 144

□ □

A 26-year-old male presented to the Emergency Department with increasing shortness of breath. Prior to his presentation two weeks ago he presented to his GP with three episodes of frank haematuria which was treated empirically with trimethoprim 200mg BD for one week as a suspected urinary tract infection. He since complained of shortness of breath starting two days ago initially affecting mild exertion but progressively increasing in severity. At the time of presentation he was short of breath at rest and unable to complete a full sentence. Whilst in hospital he was noted to cough small amounts of bright red blood on four occasions. Other than a past medical history of asthma for which he used Clenil modulite 200mcg BD inh and salbutamol PRN he was otherwise fit and well. He smoked 15 cigarettes per day and consumed 40 units of alcohol per week. There was no family history of note, and he recently returned from a holiday in Spain a few weeks ago. There was no history of exposure to tuberculosis.

On examination he was severely tachypnoeic at rest. His heart rate was 125 bpm, respiratory rate 28/min, temperature 37.6°C, oxygen saturations 92% on 15l/min of oxygen and blood pressure 108/78 mmHg. Examination of the cardiovascular examination revealed the presence of a rapid regular tachycardia with cool clammy peripheries. Respiratory examination revealed the presence of bilateral crackles and bronchial breathing in the lower zones. Gastrointestinal and neurological examination were unremarkable.

Initial investigations revealed the following:

Hb	78 g/l
MCV	78 fl
Platelets	486 * 10 ⁹ /l
WBC	11.0 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	6.2 mmol/l
Urea	26 mmol/l
Creatinine	520 µmol/l
Glucose	6.6 mmol/l

ECG: heart rate 128bpm sinus tachycardia
Chest x-ray: bilateral patchy alveolar shadowing affecting lower zones

Urinalysis: blood ++++ protein +++ glucose negative leucocytes/nitrites negative ketones ++

ABG on 15l/min of oxygen:

PaO2	6.2 kPa
PaCO2	1.8 kPa
PH	7.52
HC03-	26 mmol/l

He was quickly transferred to the intensive care unit. Which is the single most appropriate initial management strategy?

	Commencement of intravenous meropenem therapy
	High dose intravenous corticosteroid therapy
	Rapid induction cyclophosphamide therapy
	Infusion of intravenous immunoglobulin
	Repeated plasmapheresis

□ Question 141 of 144

□ □

A 67 year old man is admitted electively for an inguinal hernia repair. He has a history of hypothyroidism, aortitis and hypertension. His regular medication consists of levothyroxine 75 micrograms daily, mycophenolate mofetil 1 gram twice daily, prednisolone 5mg daily maintenance, ramipril 5mg daily and amlodipine 5mg daily. He has no known allergies. His operation went well with no intra-operative complications.

The next morning his bloods show:

Sodium	139 mmol/L
Potassium	5.6 mmol/L
Urea	15.5 mmol/L
Creatinine	342 micromol/L

His pre-operative values were:

Sodium	137 mmol/L
Potassium	4.4 mmol/L
Urea	6.2 mmol/L
Creatinine	121 micromol/L

When you review the observations he has had an adequate blood pressure throughout the operation and since. He appears euvolaemic clinically with adequate urine output. He had suspended his mycophenolate therapy two weeks prior to the operation as instructed by his consultant in rheumatology. Otherwise his medications were prescribed as above with some additional analgesia including tramadol and ibuprofen as required. You decide to suspend his nephrotoxic drugs and repeat his bloods the next morning.

According to NICE guidelines on the management of acute kidney injury (AKI), which of the following should trigger a referral to nephrology?

	AKI on a background of chronic kidney disease (CKD) stage 2 or more
	AKI in patients over the age of 65 years
	AKI in a patient with known vasculitis
	AKI caused by nephrotoxic drugs, eg, non steroidal anti inflammatory drugs
	AKI caused by hypovolaemia

Question 142 of 144

□ □

A 49-year-old known rheumatoid arthritis patient is admitted via the emergency department with a one-month history of intermittent left flank pain and bloody urine. She has had no diarrhoea or rectal bleeding. She has been a bit tired over the last few months and recently saw her GP because she was worried her ankles were swollen. She has a past medical history of hypertension. Her regular medication is penicillamine and valsartan. On examination, her abdomen is soft with mild left flank tenderness. There is no palpable hepatosplenomegaly. She has pitting oedema to the knee. Her urine dip shows 3+ of protein and 1+ RBCs.

Her blood tests show

Hb	118 g/l
Platelets	419 * 10 ⁹ /l
WBC	4.7 * 10 ⁹ /l

Na ⁺	133 mmol/l
K ⁺	4.3 mmol/l
Urea	28 mmol/l
Creatinine	328 µmol/l
CRP	11 mg/l

Bilirubin	17 µmol/l
ALP	89 u/l
ALT	11 u/l
Albumin	23 g/l

What is the most likely cause of her flank pain?

Question 142 of 144

□ □

A 49-year-old known rheumatoid arthritis patient is admitted via the emergency department with a one-month history of intermittent left flank pain and bloody urine. She has had no diarrhoea or rectal bleeding. She has been a bit tired over the last few months and recently saw her GP because she was worried her ankles were swollen. She has a past medical history of hypertension. Her regular medication is penicillamine and valsartan. On examination, her abdomen is soft with mild left flank tenderness. There is no palpable hepatosplenomegaly. She has pitting oedema to the knee. Her urine dip shows 3+ of protein and 1+ RBCs.

Her blood tests show

Hb	118 g/l
Platelets	419 * 10 ⁹ /l
WBC	4.7 * 10 ⁹ /l

Na ⁺	133 mmol/l
K ⁺	4.3 mmol/l
Urea	28 mmol/l
Creatinine	328 µmol/l
CRP	11 mg/l

Bilirubin	17 µmol/l
ALP	89 u/l
ALT	11 u/l
Albumin	23 g/l

What is the most likely cause of her flank pain?

	Inflammatory bowel disease
	Renal vein thrombosis
	Pyelonephritis
	Adult polycystic kidney disease
	Renal colic

Question 144 of 144

□ □

A 17 year old presents to the renal outpatient clinic complaining of 4 months of increasing malaise at school. He has been on haemodialysis three times a week for the past 10 months after his renal function deteriorated at age 13, following a diagnosis of focal segmental glomerulosclerosis. He is currently on the list of renal transplant. He denies any recent illnesses. Examination is unremarkable except for a mild systolic heart murmur. His blood tests are as follows:

Hb	8.3 g/dl
MCV	70 fl
Ferritin	28 microg/l (normal range 30-400 microg/L)
K ⁺	5.2 mmol/l
Urea	30.3 mmol/l
Creatinine	460 µmol/l

What is the most appropriate treatment?

	Red blood cell transfusion
	Erythropoietin therapy
	Oral iron replacement therapy
	Monitor haemoglobin, transfuse if haemoglobin under 8 g/l
	Prioritise for renal transplant urgently

Dashboard

□ Question 1 of 200

□ □

A 52-year-old man presents to the emergency department with shortness of breath. This started recently following a flight from Australia. He is morbidly obese and has a **past medical history** of type two diabetes mellitus, high cholesterol, hypertension and a previous cholecystectomy. He denies any leg pain or swelling and denies any chest pain. Observations are stable, and an **ECG** demonstrates sinus rhythm. A **chest X-ray** is clear. He undergoes a **CT pulmonary angiogram (CTPA)** to exclude a pulmonary embolus (PE). The CTPA is reported as finding no evidence of PE but notes a 7mm pulmonary nodule in the left lower lobe.

How should the pulmonary nodule be investigated or monitored?

<input type="checkbox"/>	Urgent CT-PET
<input type="checkbox"/>	Urgent image-guided biopsy
<input type="checkbox"/>	CT chest in three months
<input type="checkbox"/>	CT chest in one year
<input type="checkbox"/>	No further investigations needed

□ Question 5 of 200

□ □

A 60-year-old man, recently diagnosed to have seropositive rheumatoid arthritis presented with progressive shortness of breath and dry cough for the past 3 weeks. He was started on methotrexate at a dose of 10 mg per week, 2 months back by his treating physician.

On examination, his pulse rate was 120/min, respiratory rate was 24/min, blood pressure was 130/80 mmHg. His SpO₂ in room air was 88%. Auscultation of the chest showed bilateral basal crackles.

A CT chest was taken which showed bilateral diffuse ground glass changes with peripheral reticular lines and few patchy consolidative changes. The treating respiratory physician made a provisional diagnosis of methotrexate induced lung injury.

What would you suggest to prevent further lung damage?

	Folic acid supplementation
	Oxygen supplementation
	Switching from weekly to lower dose daily administration of methotrexate
	Decreasing the dose of methotrexate
	Prednisolone

Dashboard

□ Question 6 of 200

A 68-year-old man presents to the Emergency Department with a two-day history of chest pain associated with fever and a productive cough. He has a background of hypertension for which he takes amlodipine but is otherwise fit and well. The patient lives alone and smokes 5 cigarettes per day. He denies any history of alcohol or illicit drug use. There is no history of weight loss, haemoptysis, recent foreign travel or any pets.

On examination he looks unwell and is pyrexial. Cardiovascular examination reveals a heart rate of 100 beats/minute, regular and cool peripherals with a blood pressure of 100/65 mmHg. Respiratory examination shows a respiratory rate of 32 breaths/minute with oxygen saturations of 88% on room air and bronchial breathing is heard in the left lower zone. Pleuritic chest pain is also noted on the left hand side. Gastrointestinal examination is normal. The patient is disorientated in time and space but can obey commands and no neurological deficit is noted.

A chest x-ray shows consolidation in the left lower lobe but no pleural effusion is seen. Haematology and biochemistry results are shown below:

Haemoglobin	125 g/l
White cell count	14 * 10 ⁹ /l (a neutrophilia is noted)
Platelets	310* 10 ⁹ /l
Sodium	140 mmol/l
Potassium	3.7 mmol/l
Urea 8.1	mmol/l
Creatinine 146 µmol/l	
C-reactive protein 67 mg/l	

Liver function tests are unremarkable

The Emergency Department team have started the patient on oxygen and have obtained intravenous access and began resuscitation with 0.9% saline. As the medical registrar on call you are asked to form a plan for further management.

What is the most appropriate management plan for this patient?

	Begin double agent intravenous antibiotics and add an additional agent to cover for legionella while admitting to hospital
	Begin double agent intravenous antibiotics and admit to hospital
	Begin oral antibiotics and admit to a hospital
	Begin oral antibiotics and review in 1 hour with a view to discharge if clinically improving
	Begin single agent intravenous antibiotics and admit to hospital

Question 8 of 200

□ □

A 38-year-old woman is referred to the respiratory clinic due to a pulmonary nodule detected on a CT scan. She was admitted to her local hospital two months ago with aspiration pneumonia and treated with intravenous antibiotics. A chest X-ray demonstrated left-sided consolidation. She was also managed for alcohol withdrawal. She required three days of in hospital before being discharged with oral antibiotics and community alcohol liaison services to follow-up. Her GP repeated her chest X-ray six weeks following discharge and was concerned that an area of consolidation remained on the repeat chest X-ray. The GP, therefore, arranged for a CT chest which demonstrated a pulmonary nodule 5mm in diameter on the right side. There was no evidence of consolidation. How should this nodule be investigated or monitored?

	Urgent CT-PET
	Urgent image-guided biopsy
	CT chest in three months
	CT chest in one year
	No further investigations needed

□ Question 9 of 200

A 63 year old gentleman presented to the acute medical unit with a 3 day history of increasing shortness of breath and cough. He is known to have chronic obstructive pulmonary disease (COPD) and is treated as an infective exacerbation of COPD.

He has a past medical history of ischaemic heart disease, type 2 diabetes mellitus, hypothyroidism, hypercholesterolaemia, hypertension, epilepsy and osteoarthritis.

Despite nebulisers, steroids and antibiotics, he remains acutely breathless and his oxygen saturations are only 83% on air.

Blood gas analysis is as follows:

pH	7.21
pCO ₂	10.1 kPa
pO ₂	7.3 kPa
BE	-4.2 mmol/l
HCO ₃ ⁻	36 mEq/l

You opt to try non invasive ventilation (NIV) and he is transferred to the NIV unit. Initial settings on NIV are IPAP (inspiratory positive airways pressure) 10 cm H₂O and EPAP (expiratory positive airways pressure) 4 cm H₂O. He remains tachypnoeic and has oxygen saturations of 88%. His repeat blood gas after 1 hour is as follows:

pH	7.25
pCO ₂	9.9 kPa
pO ₂	9.3 kPa
BE	-4.0 mmol/l
HCO ₃ ⁻	35 mEq/l

Firstly, how would you adjust the NIV settings?

	Increase IPAP by 2 cm H2O
	Increase EPAP by 2 cm H2O
	Increase IPAP and EPAP by 2 cm H2O
	No change in settings
	Add extra inspired oxygen to NIV at 24%

Question 11 of 200

□ □

A 37-year-old lady presents to the Emergency Department with a 4-hour history of sudden-onset chest pain and dyspnoea. Her symptoms started whilst she was watching television. She describes the pain as severe, central and non-radiating. She denies a cough and haemoptysis. Her past medical history is unremarkable and her only regular medication is the oral contraceptive pill.

Examination reveals an overweight lady with a pulse rate of 114/min and a blood pressure of 101/63mmHg. Her respiratory rate is 22 and her oxygen saturations are 94% on air. Her JVP is 5cm but there is no peripheral oedema. Auscultation of the chest reveals scattered crepitations. Her heart sounds are dual with no audible murmurs. A portable chest x-ray shows clear lung fields.

A short time later the patient's blood pressure is recorded at 90/59mmHg. A bedside echocardiogram shows elevated right ventricular filling pressures with evidence of strain. What is the most appropriate management?

	Surgical embolectomy
	Alteplase
	Unfractionated heparin
	Aspirin, clopidogrel, low molecular weight heparin and furosemide
	Low molecular weight heparin

□ Question 12 of 200

□ □

A 25-year-old gentleman was referred to the outpatient infectious diseases clinic by his GP. He had recently immigrated from Pakistan a few months ago with his extended family. A couple of weeks ago his mother who lived in the same house as him was diagnosed with respiratory tuberculosis and he was accordingly advised to get 'checked up' by his GP. He felt well in himself, stating that he recovered from a cold a few weeks ago having had symptoms of nasal congestion, sore throat and a cough lasting a few days. He has since felt well, denying the presence of any further symptoms. Of note he has not lost weight, not had a fever, and did not suffer from a cough or night sweats. He was unsure what immunisations he had whilst in Pakistan. As a precautionary measure, the GP referred him to the infectious diseases clinic given the close proximity with his mother.

Examination revealed a well looking 25-year-old gentleman. His temperature was 36.6°C, heart rate 78 bpm, respiratory rate 16/min and oxygen saturations 99% on air. He had a BCG scar on his left arm. Examination of his cardiovascular, respiratory, gastrointestinal and neurological systems were all entirely unremarkable.

Initial investigations revealed the following:

Blood film:negative; including negative malaria screen

Blood culture: negative culture; awaiting prolonged acid-fast bacilli culture result

Quantaferon blood test: positive

Mantoux test: positive

Chest x-ray: normal appearances of heart and lung fields, no abnormality was seen

Based upon the above information, what is the next best management step?

	Commence treatment with isoniazid, pyridoxine, ethambutol, rifampicin and pyrazinamide for 2 months
	Discharge from clinic with no further action to take
	Refer for diagnostic bronchoscopy alveolar lavage
	Commence isoniazid and pyridoxine for 6 months

□ Question 14 of 200

An 82-year-old gentleman with known chronic obstructive airways disease (COPD) is about to be discharged from hospital after being admitted with an infective exacerbation. He is now off antibiotics and has just completed a seven-day course of prednisolone. He remains hypoxic on room air S_{aO_2} 91%.

Bloods show:

Hb	134 g/l
Platelets	$350 \times 10^9/l$
WBC	$10.2 \times 10^9/l$

Arterial blood gas analysis shows:

P_{aO_2}	7.8 kPa
P_{aCO_2}	6.5 kPa
HCO_3^-	30 mmol/L

The patient's wife asked about having oxygen at home. What other investigations are needed to assess whether this patient would benefit from long-term oxygen therapy?

	Oxygen saturations before and after exercise
	Pulmonary function tests
	Computed tomography (CT) of the chest
	Chest x-ray
	Echocardiogram

Dashboard

Question 16 of 200

□ □

A 66 year old gentleman, who is a known heavy smoker, presents with a non infective exacerbation of chronic obstructive pulmonary disease (COPD). Upon admission despite maximal medical therapy his blood gasses worsen and he is commenced on non invasive ventilation and transferred to the high dependency unit. The nurses call you in the middle of the night to come and urgently review the patient. They have been titrating up the patient's non invasive ventilation (NIV) as they felt his blood gasses were not improving on standard settings. On arrival the patient is diaphoretic and complaining of chest pain. He is unable to tolerate his face mask. Observations are recorded as a pulse of 110/min regular, respiratory rate 32/min, Sats 75% on air, Blood pressure 100/82 mmHg. What is the most likely cause for this patient's acute deterioration?

	Ventilator associated pneumonia
	Acute myocardial infarction
	Ventilator associated pneumothorax
	Worsening of his COPD
	Panic attack

Dashboard

Question 17 of 200

□ □

A 61 year old gentleman is reviewed in the respiratory clinic. He has a diagnosis of chronic obstructive pulmonary disease and a history of smoking which he discontinued five years prior, although not before amassing a forty pack year history. He relates four emergency admissions to hospital in the past year with exacerbations of his lung disease and is currently breathless enough to reduce his exercise tolerance by a half. He is mildly wheezy on auscultation but there is no overt clinical infection. His respiratory rate is 22 and his oxygen saturations are 93% on air. Spirometry reveals a forced expiratory volume in one second (FEV1) of 35% predicted. He is currently taking inhaled salbutamol as required and once daily inhaled tiotropium.

Which of the following is the most appropriate pharmacological management for this patient?

	Substitution of salbutamol with a long acting beta agonist (LABA)
	Addition of a long acting muscarinic antagonist (LAMA)
	Addition of combination long acting beta agonist and long acting muscarinic antagonist (LABA/LAMA)
	Addition of combination long acting beta agonist and inhaled corticosteroid (LABA/ICS)
	Addition of inhaled corticosteroid therapy (ICS)

Dashboard

□ Question 18 of 200

□ □

A 60-year-old woman is investigated for recurrent episodes of dyspnoea. She describes becoming progressively more short-of-breath over the past two years with frequent exacerbations associated with fever, lethargy and coughing bouts. Her symptoms often settle down for a time but she does feel her breathing is getting worse over time.

She smokes 20 cigarettes/day, drinks 10 units of alcohol per week and works in a poultry farm. Her past medical history includes hypothyroidism and depression.

On examination her oxygen saturations on air are 94%.

A CT scan is requested:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Bronchiectasis
	Hypersensitivity pneumonitis
	Sarcoidosis
	Histiocytosis
	Histoplasmosis

Question 21 of 200

□ □

A 68-year-old is seen in a cardiology clinic. He has a part history of long-standing atrial fibrillation, hypertension and ischaemic heart disease. He describes progressive shortness of breath over the past year and a dry cough. His medication history includes aspirin, amiodarone, ramipril, doxazosin and gliclazide.

On examination, he is comfortable on lying flat but is noticeably dyspnoeic when mobilising. He has minimal ankle oedema, his heart rate is 78 beats per minute and he has fine bibasal crepitations on auscultation of his chest. His oxygen saturations on air are 92%.

An echocardiogram reveals a left ventricular ejection fraction of 45%, a mildly hypertrophied left ventricle and well established right ventricular hypertrophy, pulmonary artery pressures are raised at 32 mmHg (normal: < 25 mmHg). A chest x-ray shows non-specific changes on both bases.

What is the most appropriate next investigation?

	Exercise stress test
	Cardiac MRI
	Overnight oximetry
	Repeat echo
	HRCT chest

Dashboard

Overall score: 0%

Question 22 of 200

□ □

A 76-year-old man presented with vague lower abdominal pain. He was known to have underlying type 2 diabetes mellitus, hypertension and severe chronic obstructive pulmonary disease (COPD). He was a smoker with 50 pack years smoking history.

A CT abdomen was taken which showed diverticular disease of the colon. Incidentally it also showed a 2.5 cm mass in the periphery of the lower lobe of the left lung. Subsequently he underwent a positron emission tomography (PET) scan which showed the lung lesion with standardised uptake value (SUV) of 12.5 which was highly suspicious of cancer. There was no evidence of spread to lymph nodes or distant sites. A CT guided biopsy of the lung lesion was done which showed squamous cell carcinoma. His performance status was 2 in Eastern Cooperative Oncology Group (ECOG) scale. His lung functions showed an FEV1 of 0.8L (25% predicted) and FVC of 1.3L (30% predicted). TLCO was 30% predicted.

Which of the following is a suitable choice of treatment for him?

	Lobectomy
	Chemotherapy
	Radical radiotherapy
	Lobectomy+chemotherapy
	Best supportive care

Dashboard

She has slight associated pleuritic chest pain, but no cough and denies coughing up any blood and denies feeling hot or cold. Her symptoms started four hours ago and came on suddenly whilst at rest. She was well prior to today.

She has a past medical history of hypothyroidism and underwent a wide local excision for ductal carcinoma in situ one year ago. Her observations are all within normal range except for oxygen saturations which are at 93%. She has never smoked. Chest examination reveals few scattered crepitations heard over the right lower zone. Blood tests, including a D-dimer, are pending. What is the most appropriate next step?

	Warfarin
	Chest X-ray
	CT pulmonary angiogram
	Ventilation-Perfusion scan
	Treatment dose low molecular weight heparin

□ Question 24 of 200

□ □

A 72-year-old gentleman presents for review in the medical clinic. He has had COPD for five years and is on regular bronchodilator treatment with a combination budesonide and formoterol fumarate inhaler and salbutamol inhaler as needed. He has found that he suffers from multiple chronic coughs and finds his exercise tolerance reduced. He has a past medical history of macular degeneration, osteoarthritis, mild memory impairment and diverticulosis. He has noticed that the distance he can walk has reduced from being able to go to the local shop, roughly one mile away, to having to stop at three-quarters the distance there. What would investigation result be most useful to help determine the severity of his COPD?

	FEV1/FVC
	Chest X-ray
	High resolution CT scan of the chest
	Partial pressure of oxygen on arterial blood gas
	FEV1% of predicted

□ Question 25 of 200

□ □

A 62 year old woman is referred for a respiratory opinion after experiencing a 6 month history of increasing shortness of breath on exertion. Initially symptoms were mild but had progressed to the point where climbing a single flight of stairs leaves the patient requiring to sit and rest to catch her breath. There was no history of cough, chest pain or sputum production. Treatment with two courses of antibiotics prescribed by her GP had no effect on her symptoms. Past medical history included a hysterectomy at the age of 50 years and hypertension, treated with bendroflumethiazide for the past 12 months. The patient is a retired bank clerk and is a carer for her husband. She has never smoked and drinks around 15 units of alcohol per week.

Examination revealed no finger clubbing but persistent bi-basal crackles were present on auscultation of the lower zones. Cardiovascular examination demonstrated no elevation of jugular venous pressure, no right ventricular heave, normal heart sounds and no peripheral oedema. Painless swelling of the distal interphalangeal joints of the patient's right index and ring fingers was noted.

Details of initial investigations are given below.

Rheumatoid factor	Negative
Anti-nuclear antibodies	Negative
Erythrocytes sedimentation rate	65 mm / hr

Forced vital capacity	55 % predicted
Forced expiratory volume (1s)	52 % predicted
FVC / FEV1	97 % predicted
TLCO	45 % predicted
DLCO	47 % predicted

High resolution CT chest: sub-pleural reticular interstitial shadowing predominant in the lung bases

Transthoracic echocardiogram: normal systolic and diastolic function of both right and left ventricles; normal valvular function; normal pulmonary artery pressures

What treatment has been demonstrated to reduce the risk of disease progression in this patient?

	N-acetyl cysteine
	Co-trimoxazole
	Nintedanib
	Azathioprine
	Pirfenidone

Dashboard

□ Question 27 of 200

□ □

A 22 year old agricultural student presents to a Respiratory clinic with cough, breathlessness, fatigue with weight loss of 2 kg for 6 weeks. Examination reveals bilateral wheeze and crackles. His GP has tried 2 courses of antibiotics and Salbutamol inhaler with no real benefit; he had some relief from a short course of oral prednisolone. He denies any fever, haemoptysis, foreign travel or exposure to TB. He has never smoked.

His chest radiograph shows mid to upper zone alveolar fine nodular shadowing bilaterally. His lung function shows a FVC (forced vital capacity) of 70% and FEV1/FVC of 85% predicted. Bloods show:

CRP	3 mg/l
ESR	45mm/hr

What is the most likely diagnosis?

	Pulmonary embolus (PE)
	Community acquired pneumonia
	Asthma
	Extrinsic allergic alveolitis
	Silicosis

Dashboard

□ Question 28 of 200

A 57-year-old woman, originally from Thailand, presents with a 3 week history of haemoptysis, a dry irritating cough and progressive shortness of breath that has reduced her ability to climb stairs and walk distances greater than roughly 50 meters. She has no other medical history of note apart from an appendectomy when younger. She takes no regular medication except for over the counter herbal remedies that she gets from a local Chinese medicine shop, although she cannot remember what these are called. She smokes 10 cigarettes per day and does not drink alcohol.

Examination reveals heart sounds 1 and 2 present with no added sounds. Some crackles across the chest. Observations are normal.

Blood tests reveal:

Hb	99 g/l
MCV	74 fL
Platelets	$196 \times 10^9/l$
WBC	$14.8 \times 10^9/l$
Na ⁺	133 mmol/l
K ⁺	5.0 mmol/l
Urea	15 mmol/l
Creatinine	193 μ mol/l
ESR	92 mm/hr

A chest x-ray is performed which reveals some diffuse alveolar infiltrates but no focal areas of consolidation. A sputum sample is analysed for MC and S and shows no malignant cells.

What is the most likely diagnosis?

	Polyarteritis nodosa

	Pulmonary embolism
	Goodpasture's syndrome
	Churg-Strauss syndrome
	Sarcoidosis

Dashboard

Question 29 of 200

□ □

A 55-year-old, non-smoker presents to the Emergency Department with sudden onset pleuritic chest pain. He has no documented history of lung disease and is a non-smoker. On examination, he had reduced air entry on the right with bilateral fine end-inspiratory crepitations to the midzones. He is clubbed. A chest x-ray confirms a right sided pneumothorax, measuring 0.5 cm at the hilum. He is not breathless and peripheral oxygen saturations are 94% on air.

What would be the correct course of action?

	Insert a Seldinger chest drain
	Discharge with clinic follow up in 2-4 weeks
	Discharge without follow up
	Aspirate up to 2.5L and repeat chest x-ray
	Admit for 24 hours with conservative treatment

Dashboard

Overall score: 0%

□ Question 30 of 200

□ □

A 66 year old retired farmer presents with a 4 week history of increasing shortness of breath, non-specific non-pleuritic chest pain and weight loss. His past medical history includes previous angina, for which he was previously prescribed a GTN spray that he has not required for 3 years and hypertension. He is known to keep racing pigeons in a barn on his property. He keeps active and lives with his wife, drinks moderate amount of alcohol and is an active smoker with a 40 pack year history. He has no known allergies. On examination, you note bilateral clubbing and tar staining. Respiratory examination revealed a respiratory rate of 19 breaths per minute, sats 94% on air, reduced bilateral chest expansion and reduced air entry in both bases associated with dullness to percussion.

A chest radiograph demonstrates moderate right >left bilateral pleural effusions and patchy opacities across both lung fields in a non-lobar distribution. CT thorax with high resolution slices demonstrates bilateral pleural effusion, thickened pleura with no lung parenchyma abnormalities.

Lung function testing demonstrates FEV1 1.7ls, FVC 55% of predicted.

What is the appropriate next investigation?

	CT chest/abdomen/pelvis with contrast
	High resolution CT chest (HRCT)
	Video assisted thoracoscopic biopsy (VATS)
	Chest drain
	Bronchoscopy with bronchoalveolar lavage (BAL)

Dashboard

Overall score: 0%

□ Question 31 of 200

□ □

A 74-year-old male presents to the acute medical take with left sided chest pain, worse on inspiration. On examination, you note his nails are yellow and clubbed with bilateral non-pitting oedema. Examination of his chest reveals reduced air entry of his left lung to mid zone, dull to percussion, with no wheeze.

He has a known past medical history of bronchiectasis diagnosed 2 years ago, for which he has been admitted 3 times in the past 5 months. He reports weight loss of about 8kg in the past 9 months. He last underwent an echocardiogram 2 years ago, during which a left ventricular ejection fraction of 56% was demonstrated.

A chest radiograph demonstrates a large left pleural effusion and a mark has been made by ultrasound for a pleural tap.

Pleural fluid analysis results are as follows:

pH	7.42
Protein	40 g/L (serum 58)
LDH	130 IU/L (serum 181)
Glucose	3.5 mmol/l (serum 6.2)
Amylase	22 u/l (serum 32)
Triglycerides	1.90 mmol/L (serum 2.2)
Cytology	awaited
AFB	awaited

What is the unifying diagnosis?

	Parapneumonic effusion
	Yellow nail syndrome

	Malignant pleural effusion
	Oesophageal rupture
	Congestive cardiac failure

Dashboard

Examination of his chest reveals reduced air entry of his left lung to mid zone, dull to percussion, with no wheeze.

He has a known past medical history of bronchiectasis diagnosed 2 years ago, for which he has been admitted 3 times in the past 5 months. He reports weight loss of about 8kg in the past 9 months. He last underwent an echocardiogram 2 years ago, during which a left ventricular ejection fraction of 56% was demonstrated.

A chest radiograph demonstrates a large left pleural effusion and a mark has been made by ultrasound for a pleural tap.

Pleural fluid analysis results are as follows:

pH	7.42
Protein	40 g/L (serum 58)
LDH	130 IU/L (serum 181)
Glucose	3.5 mmol/l (serum 6.2)
Amylase	22 u/l (serum 32)
Triglycerides	1.90 mmol/L (serum 2.2)
Cytology	awaited
AFB	awaited

What is the unifying diagnosis?

	Parapneumonic effusion
	Yellow nail syndrome

	Malignant pleural effusion
	Oesophageal rupture
	Congestive cardiac failure

□ Question 33 of 200

A 64 year-old female patient with known chronic obstructive pulmonary disease presents for routine review at respiratory outpatients. She is currently taking inhaled tiotropium and salmeterol/fluticasone at optimal doses. You note she has had two exacerbations in the previous 12 months requiring oral steroids and antibiotics. A recent high resolution CT showed severe emphysema affecting all lobes.

Her ABGs in clinic today is a follows:

pH	7.38
pO ₂	7.91 kPa
pCO ₂	6.7 kPa
HCO ₃	30.1 mmol/L
Sats	88%

Her blood tests today show:

Hb	16.6 g/dL
Platelets	256 x 10 ⁹ /L
WCC	6.7 x 10 ⁹ /L

How would you optimise her management further?

<input type="checkbox"/>	Refer to lung volume reduction surgery
<input type="checkbox"/>	Make no changes to current management
<input type="checkbox"/>	Consider long term oxygen therapy
<input type="checkbox"/>	Start prophylactic antibiotics

	Refer for assessment for home non-invasive ventilation

□ Question 35 of 200

□ □

A 73-year-old gentleman presents to oncology clinic with a two-week history of shortness of breath. He has a background of mesothelioma diagnosed two years ago. He has noticed that he has been finding it more difficult to walk distances without developing shortness of breath, and today struggled to make it into the clinic from the car-park, 200 yards away. He denies having a cough or fever but has been feeling more tired lately. Saturations are 95% whilst breathing room and his blood pressure, temperature, heart rate and respiratory rate are all within normal parameters.

A chest X-ray is done which demonstrates a right-sided pleural effusion. He is admitted to hospital and a chest drain is inserted, draining three litres of blood-stained fluid in two hours. He becomes increasingly short of breath and starts to cough. He denies any chest pain. On examination, he is uncomfortable and breathing 4L of oxygen via a non-rebreather mask. There are bilateral crepitations in his chest.

	25/11/16 16:31	25/11/16 14:18
Saturations	91%	95%
Respiratory rate	22/min	18/min
Blood pressure	131/81mmHg	139/85mmHg
Heart rate	101/min	71/min
Temperature	37.0°C	37.1°C

What is the likely diagnosis?

	Empyema
	Iatrogenic chest infection
	Re-expansion pulmonary oedema
	Pneumothorax
	PE

Question 36 of 200

□ □

A 62-year-old gentleman presents to clinic with increasing shortness of breath on exertion. His symptoms have progressed over three months and he has now become concerned as he is struggling to walk through the park without stopping to catch his breath. He has also noticed a new, raised lesion on his chin. He has a few unexplained temperatures within the last week as well and has noticed mild joint pain. He assumed that the latter was arthritis but has not suffered from this before. He has a past medical history of hypertension, glaucoma and has been hospitalised with pneumonia within the last year.

On examination, he has a 1cm wide, raised lesion on his chin which is purple in colour with some telangiectasia. He does not have a fever currently and his observations are all within normal limits. There is no finger clubbing. There is bilateral cervical lymphadenopathy and auscultation demonstrates bibasal fine inspiratory crackles. These do not shift with coughing. A chest X-ray is requested. What is it most likely to show?

	Cavitating lesion
	Pleural effusion
	Bilateral consolidation
	Bilateral hilar lymphadenopathy
	Apical fibrosis

Dashboard

Question 37 of 200

A 24 year-old male with no significant past medical history presents with a 4 hour history of chest pain and breathlessness. The pain is right sided and is sharp in nature, worsening on deep inspiration.

There is no significant past medical history. On examination he is tachypnoeic with a respiratory rate of 26 breaths per minute. His oxygen saturations are 97% on room air. His pulse rate is 100bpm with a blood pressure of 136 / 82mmHg. A 12-lead ECG reveals sinus tachycardia with a rate of 102 beats per minute.

Arterial blood gas analysis reveals:

pO ₂	11.8kPa
pCO ₂	4.3 kPa
pH	7.45
Bicarbonate	24mEq/L

A chest radiograph reveals a right-sided pneumothorax 1.8cm in width at the level of the hilum.

What is the most appropriate initial management?

<input type="checkbox"/>	High-flow oxygen
<input type="checkbox"/>	Pleural aspiration
<input type="checkbox"/>	Observe for 24 hours
<input type="checkbox"/>	Insert chest drain
<input type="checkbox"/>	Talc pleurodesis

□ Question 38 of 200

A 68-year-old man presents to hospital with progressive shortness of breath over the last four days and a low-grade fever. He has a past medical history of mild asthma for which he occasionally needs to use his salbutamol inhaler and has previously had bilateral knee replacements for osteoarthritis. He has smoked on average 5 cigarettes per day for the past 40 years and drinks a couple of glasses of wine per week. His travel history includes a holiday to Cyprus, from which he arrived back in the UK 5 days ago.

Examination revealed some right mid zone crackles and reduced breath sounds over this area. Observations revealed a temperature of 38.8°C, heart rate of 110 bpm, blood pressure of 105/66 mmHg, respiratory rate of 22 breaths per minute and oxygen saturations of 91% on room air.

Blood tests revealed:

Hb	145 g/l
Platelets	290 * 10 ⁹ /l
WBC	9.4 * 10 ⁹ /l
Na ⁺	132 mmol/l
K ⁺	3.7 mmol/l
Urea	4.1 mmol/l
Creatinine	67 µmol/l

Urinary sodium concentration was measured and found to be 36mmol/L (normal range 40-220 mmol/d). Which of the following investigations is most useful in the diagnosis of this condition?

	Urine antigen test
	Serum antibody test
	Sputum PCR

	CT pulmonary angiography
	D-dimer

Question 39 of 200

□ □

A 60-year-old man presented to the sleep clinic with snoring, excessive day time sleepiness and fatigue. His partner also mentioned that she could see him choking on and off during sleeping and that scared her. He also had underlying hypertension, arrhythmia and osteoarthritis of bilateral knee joints. He drove a car but never had any accidents.

On evaluation, his epworth sleepiness score was 15/24. His BMI was 44, modified mallampati score was class 3. Clinically, obstructive sleep apnoea(OSA) was suspected and he underwent a polysomnography which showed an apnoea hypopnoea index(AHI) of 60/hour. Most of the events were in supine position and during rapid eye movement(REM) sleep. Lowest SpO2 during sleep was 80%.

He was started on continuous positive airway pressure(CPAP) trial but he could not tolerate it and did not want to continue it in spite of repeated counselling and trying different masks. What would you suggest him?

	Weight reduction
	Positional therapy
	Oral appliance
	Modafinil
	Cognitive behavioral therapy

Dashboard

Question 41 of 200

A 76 year old woman presents to clinic with shortness of breath. This has been progressing over the last 18 months and is associated with a non-productive cough. She is still able to complete her usual day-to-day tasks, but struggles with more exertional activities such as gardening.

She finished chemotherapy for non-Hodgkin's lymphoma two years ago. She has no other relevant medical history.

Her current medications include allopurinol, bisoprolol, aspirin, simvastatin, paracetamol and codeine.

On examination, she has finger clubbing and diffuse fine crackles on chest auscultation.

Given the likely diagnosis, which of the following spirometry results would you expect?

	FEV1 - 1.4L (71%), FVC - 2.5L (102%), FEV1/FVC ratio - 56%, DLCO - 90% of predicted
	FEV1 - 1.3L (66%), FVC - 1.6L (65%), FEV1/FVC ratio - 81%, DLCO - 75% of predicted
	FEV1 - 1.9L (97%), FVC - 2.4L (98%), FEV1/FVC ratio - 79%, DLCO - 110% of predicted
	FEV1 - 0.9L (45%), FVC - 2.1L (86%), FEV1/FVC ratio - 42%, DLCO - 90% of predicted
	FEV1 - 0.9L (45%), FVC - 1.1L (45%), FEV1/FVC ratio - 81%, DLCO - 120% of predicted

□ Question 43 of 200

□ □

A 54-year-old woman presents to the Acute Medical Unit with a three day history of fever, myalgia and a non-productive cough. She initially thought her symptoms were due to the 'flu but over the past 24 hours has been feeling progressively more poorly. She now also has nausea, abdominal pain, headaches and diarrhoea.

On examination her pulse is 84/min, temperature 39.4°C and blood pressure 106/76 mmHg. Bilateral scattered crackles are noted on auscultation.

Bloods show the following:

Hb	12.4 g/l	Na ⁺	133 mmol/l
Platelets	363 * 10 ⁹ /l	K ⁺	5.0 mmol/l
WBC	12.1 * 10 ⁹ /l	Urea	7.8 mmol/l
Neuts	10.8 * 10 ⁹ /l	Creatinine	88 µmol/l
Lymphs	1.1 * 10 ⁹ /l	CRP	145 mg/l
Eosin	0.2 * 10 ⁹ /l		

The chest x-ray is shown below:

Which investigation is most likely to be diagnostic?

	Sputum culture
	Cold agglutinins
	Bronchoalveolar lavage
	Blood serology
	Urinary antigen

□ Question 45 of 200

□ □

A 67-year-old female patient presents to respiratory outpatients having been referred by her GP with increasing breathlessness. The referral letter mentions she has received 2 courses of antibiotics for chest infections in the last year and a 50 pack year smoking history. The patient complains of a productive cough with occasional streaks of blood but no history of weight loss. Her past medical history includes cardiac failure treated with enalapril, bisoprolol and furosemide, recurrent urinary tract infections treated with long-term nitrofurantoin and osteoarthritis treated with paracetamol and meptazinol. On examination, there is bilateral scattered coarse crepitations and finger clubbing.

Spirometry in clinic is as follows:

Forced vital capacity (FVC)	1.99L (72% predicted)
Forced expiratory volume in 1 second (FEV1)	1.20L (52% predicted)
FEV1/FVC ratio	0.60

What is the likely diagnosis?

	Bronchiectasis
	Chronic obstructive pulmonary disease
	Pulmonary fibrosis
	Squamous cell carcinoma
	Congestive cardiac failure

Question 46 of 200

A 59-year-old gentleman is brought in by ambulance to the emergency department with severe shortness of breath. He is unable to speak in full sentences or give much of a history. His partner explains that he has been coughing green phlegm for a week and started taking his rescue pack of steroids and antibiotics, but over the last 24 hours he has become more unwell with fevers and worsening chest tightness. He has a past medical history of COPD and hypertension and is normally on home inhalers but has never needed NIV, invasive ventilation, home nebulisers or home oxygen. The partner is unsure if he is known to be a carbon dioxide retainer.

He appears to be very unwell and is hypoxic and tachypnoeic. On auscultation, he sounds very wheezy throughout his chest. He has already been given IV steroids and IV antibiotics as well as controlled oxygen therapy via venturi mask at 24%. An arterial blood gas is done.

Arterial blood gas:

pH	7.25
pCO ₂	10.4kPa
pO ₂	8.9kPa
HCO ₃ ⁻	24mmol/l

What is the most appropriate immediate management plan?

<input type="checkbox"/>	CT chest
<input type="checkbox"/>	Immediate invasive ventilation
<input type="checkbox"/>	Immediate non-invasive ventilation
<input type="checkbox"/>	Medical management with nebulisers then if not improving start non-invasive ventilation
<input type="checkbox"/>	IV theophylline

Dashboard

□ Question 47 of 200

A 23-year-old woman is referred by the emergency department with sudden onset shortness of breath and pleuritic chest pain. She describes no cough or sputum. The pain is constant and not worse on movement. She is 24 weeks pregnant with her third child. She is normally fit and well and on no regular medication beyond her pregnancy supplements. On examination, she is slightly tachypnoeic at 21/min but her sats are 98% on room air. Her blood pressure is 110/78 mmHg and her heart rate is 86/min. Her chest is clear and the JVP is not elevated and her heart sounds are normal. The emergency department registrar has sent several blood tests. The results are:

Hb	118 g/l
Platelets	$443 \times 10^9/l$
WBC	$9.8 \times 10^9/l$

Trop T	6ng/L (<14ng/L excludes cardiac damage)
D-dimer	1.3 mg/L (<0.5)
CRP 16	mg/L (<10)

Her chest x-ray is unremarkable.

Her ABG shows:

pH	7.39
pO ₂	8.6kPa
pCO ₂	2.9kPa
HCO ₃ ⁻	21mmol/L (22-29)
Sats	97%
BE	1.1

She is seen on the post take ward round and the Consultant would like to exclude a pulmonary embolism.

What is the most appropriate first investigation for this lady?

	Half dose CTPA
	V/Q scan
	USS Doppler of legs
	Full dose CTPA
	No need for investigation treat with LMWH

Dashboard

Question 54 of 200

□ □

A 69-year-old man from Pakistan presents to his general practitioner with a three month history of cough associated with episodes of haemoptysis and has had some episodes of shortness of breath. His only past medical history of note is asthma for which he takes salbutamol inhaler as required and 2 puffs of beclomethasone inhaler twice daily. He has a 25 pack-year history and he is teetotal. The patient's GP performs blood tests and refers the patient to the rapid access chest clinic.

Blood test results come back as all within normal reference ranges, however, chest x-ray shows a solid lesion at the apex of the right lung, that is associated with a rim of air.

Of the following options, which is the most likely diagnosis?

	Tuberculosis
	Mesothelioma
	Aspergilloma
	Squamous cell carcinoma
	Small cell lung carcinoma

□ Question 55 of 200

□ □

A 71-year-old retired bus driver is referred to the respiratory fast-track clinic. He saw his GP after 2 months of right-sided chest pain and cough. He received a course of amoxicillin with some improvement in the cough and chest pain but has since started getting short of breath when just walking around the house. He is an ex-smoker of 30 pack-years.

On assessment, he has dullness to percussion and reduced air entry on the right lung base. His saturations are 96% on air. Chest x-ray confirms a right pleural effusion. Pleural ultrasound shows a moderate sized simple effusion. A pleural aspirate is performed:

Appearance	Serosanguineous
pH	7.32
Protein	45 g/l
LDH	450 IU/l
Glucose	4.0mmol/l
Gram stain	No organisms or malignant cells seen
Culture	No growth

Given the clinical scenario and results so far, what is the next best step for investigation of this patient?

	Surgical VATS for pleural biopsy
	CT thorax with contrast
	Further course of antibiotics
	Intercostal drain
	Observe and repeat chest x-ray and pleural ultrasound in 4 weeks

Dashboard

□ Question 56 of 200

□ □

A 58-year-old man presents to the emergency department with a three-day history of sharp chest pain. He denies any shortness of breath. His pain is worse on deep inspiration and has not improved with paracetamol. He has no other symptoms. He has a past medical history of COPD and uses regular combination inhalers with salbutamol inhalers when he becomes short of breath. He has not recently had an exacerbation and he has never been admitted to ITU or had invasive ventilation. Examination demonstrates no abnormalities; the chest is clear on auscultation and vital parameters are within normal range. A chest X-ray demonstrates a <1cm right-sided pneumothorax. He is treated with high flow oxygen. What is the benefit of oxygen in the treatment of a pneumothorax?

	Maintaining pressure inside alveoli to prevent further expansion of pneumothorax
	Exchange of nitrogen for oxygen allowing quicker resorption of the pneumothorax
	Prophylactic treatment if suddenly becomes hypoxic
	There is no indication for oxygen
	Symptomatic relief

Dashboard

□ Question 57 of 200

□ □

A 79-year-old man is seen in the respiratory clinic after being referred by his GP. He is has been getting progressively more short-of-breath for the past 2 years and now struggles to climb the stairs at home.

He gave up smoking 5 years ago after having a 50-pack-year history. He drinks around 20 units of alcohol per week and is a retired coal miner.

On auscultation he has scattered fine crackles, predominately in the upper zones. Oxygen saturations on room air are 91%. Spirometry shows the following;

FEV1	1.4 L (predicted 3.8 L)
FVC	1.7 L (predicted 4.5 L)
FEV1/FVC	82% (normal > 75%)

A chest x-ray is requested:

□ Question 58 of 200

□ □

A 23-year-old man presents to the emergency department with shortness of breath, fever and a cough. He has been having a non-productive cough for two weeks. Prior to this, he felt had felt unwell with muscle aches and malaise. He went to his GP and was given amoxicillin but this has made no difference and now he is feeling more breathless and unwell. He travelled to Belgium one month ago but apart from that has not been outside of the UK. He has no other medical problems and takes no regular medications. His cough is non-productive and comes in paroxysms which make him concerned.

On examination, there are a few bilateral crepitations but the examination is otherwise normal. His observations show fever and mild hypoxia. Blood tests show mild anaemia and raised inflammatory markers. A chest X-ray shows bilateral consolidation, but he improves with IV co-amoxiclav and clarithromycin over a few days. What is the most likely causative organism?

	Klebsiella pneumoniae
	Legionella pneumophila
	Mycoplasma pneumoniae
	Chlamydia psittaci
	Coxiella burnetii

Question 59 of 200

□ □

A 60-year-old man comes to his GP complaining of cough and dyspnoea on exertion. He has had the cough for over 2 years, but it has gotten worse recently along with increasing shortness of breath. He has no haemoptysis, chest pain or leg swelling. The patient has a 60 pack-year smoking history and drinks a moderate amount of alcohol. His temperature is 37.2°C, blood pressure is 140/80 mmHg, pulse is 80/min, and respirations are 20/min.

Chest x-ray shows prominent bronchovascular markings and mild diaphragmatic flattening.
Pulmonary function test results are as follows:

Forced expiratory volume in 1 second	67% of predicted
Forced vital capacity	95% of predicted
FEV1/FVC ratio	0.65

Carbon monoxide diffusion capacity is 100% of predicted value.

Which of the following is the most likely cause of this patients symptoms?

	Asbestosis
	Chronic bronchitis
	Panacinar emphysema
	Pulmonary fibrosis
	Rheumatoid lung

Question 60 of 200

□ □

A 66-year-old man, presented with two episodes of mild haemoptysis in the past 3 months. He also had lost 5 kilograms of weight in the past 3 months. He was a smoker with 50 pack years history and a social drinker. He was actively mobile and had no significant past medical history.

Clinical examination revealed no abnormality except clubbing.

A contrast enhanced CT chest showed a 4 cm mass in the right upper lobe periphery close to the chest wall and enlarged right hilar (2 cm) and subcarinal (2 cm) lymph nodes. A positron emission tomography (PET) scan was done which showed a standard uptake value (SUV) max of 20 for the lung mass. The ipsilateral hilar and subcarinal lymph nodes were also found to be FDG (fluorodeoxyglucose) avid. There was no evidence of distant metastasis.

What is the next appropriate step in the management?

	CT guided biopsy of the lung mass
	Ultrasound guided biopsy of the lung mass
	Flexible bronchoscopic biopsy of the lung mass
	Endobronchial ultrasound (EBUS) guided mediastinal lymph node sampling
	Video-Assisted Thoracoscopic Surgery (VATS) biopsy of the mediastinal lymph nodes

□ □

An 83-year-old female presents to A&E with a four day history of increasing shortness of breath and worsening of a chronic productive cough. She speaks no English but you know from her medical records that she recently emigrated from rural India to live with her family two years ago. She has no diagnosed underlying lung condition. On examination, she has bilateral expiratory wheeze and hyperexpanded lungs with no clear inspiratory crackles. Heart sounds appear normal and mild bilateral pitting oedema. Her saturation measures 88% on air via pulse oxymeter, respiratory rate is 24 to 28 per minute. Her chest radiograph is hyperexpanded with mild bibasal fibrotic changes but demonstrates no focal signs of consolidation. She has no smoking or alcohol history. Her blood tests are as follows:

Hb	15.0 g/dl
Platelets	211 * 10 ⁹ /l
WBC	11.4 * 10 ⁹ /l
Neutrophils	9.5 * 10 ⁹ /l

Urea	8.4 mmol/l
Creatinine	112 µmol/l
CRP	37 mg/l

What is the most likely diagnosis?

	Exacerbation of congestive cardiac failure
	Infective exacerbation COPD
	Community acquired pneumonia
	Tuberculosis
	Progression of pulmonary fibrosis

Dashboard

□ Question 62 of 200

□ □

A previously well 28-year-old man presents with shortness of breath and abdominal discomfort. He reports a dry cough for the previous 10 days. He works full time as a management consultant. He is a non-smoker and drinks approximately 20 units of alcohol a week. He went on a stag-do to Prague with a bunch of friends 2 weeks ago. In the last few days, he has noticed a widespread skin rash which he describes as lots of pink rings around a pale centre.

Bloods on admission:

Na ⁺	128 mmol/l
K ⁺	3.7 mmol/l
Urea	8.2 mmol/l
Creatinine	150 µmol/l

Chest x-ray: Diffuse reticular infiltrates and small right-sided pleural effusion.

What is the most likely causative organism?

	<i>Staphylococcus aureus</i>
	<i>Pneumocystis jirovecii</i>
	<i>Mycoplasma pneumoniae</i>
	<i>Streptococcus pneumoniae</i>
	<i>Haemophilus influenzae</i>

Overall score: **0%**

□ Question 64 of 200

A 65-year-old man presents to the respiratory clinic with worsening haemoptysis the past 3 months. He is also concerned as he has noticed a loss of 6kg in the past 2 months. He previously completed a course of tuberculosis (TB) treatment 20 years ago, and he is currently a smoker, with a 50 pack year history.

On examination he is cachectic. Temperature is 36.8°C, heart rate 80 bpm, respiratory rate 18 breaths per minute. There are decreased breath sounds and dullness to percussion over the right upper lobe, and conjunctival pallor. His fingers are clubbed. The rest of his examination is unremarkable.

Investigations:

Na+	131 mmol/l
K+	4.3 mmol/l
Urea	6.1 mmol/l
Creatinine	102 µmol/l
Serum corrected calcium	2.35 mmol/l
Serum bilirubin	21 µmol/l
Serum alkaline phosphatase	85 IU/l
Serum aspartate aminotransferase	16 IU/l
C Reactive protein (CRP)	15 mg/l
Haemoglobin	110 g/l
Mean Corpuscle Volume	77 fL
White cell count	$11.2 \times 10^9/L$
Neutrophils	$7.5 \times 10^9/L$
Eosinophils	$1.9 \times 10^9/L$

□ Question 64 of 200

A 65-year-old man presents to the respiratory clinic with worsening haemoptysis the past 3 months. He is also concerned as he has noticed a loss of 6kg in the past 2 months. He previously completed a course of tuberculosis (TB) treatment 20 years ago, and he is currently a smoker, with a 50 pack year history.

On examination he is cachectic. Temperature is 36.8°C, heart rate 80 bpm, respiratory rate 18 breaths per minute. There are decreased breath sounds and dullness to percussion over the right upper lobe, and conjunctival pallor. His fingers are clubbed. The rest of his examination is unremarkable.

Investigations:

Na+	131 mmol/l
K+	4.3 mmol/l
Urea	6.1 mmol/l
Creatinine	102 µmol/l
Serum corrected calcium	2.35 mmol/l
Serum bilirubin	21 µmol/l
Serum alkaline phosphatase	85 IU/l
Serum aspartate aminotransferase	16 IU/l
C Reactive protein (CRP)	15 mg/l
Haemoglobin	110 g/l
Mean Corpuscle Volume	77 fL
White cell count	$11.2 \times 10^9/L$
Neutrophils	$7.5 \times 10^9/L$
Eosinophils	$1.9 \times 10^9/L$
Lymphocytes	$1.1 \times 10^9/L$

Basophils	0.0 x 10 ⁹ /L
Platelets	490 x 10 ⁹ /L
INR	1.0

Chest x-ray: Intracavitary mass in the right upper zone

□ Question 65 of 200

□ □

A 38-year-old male plumber is referred to the medical assessment unit by his GP due to reduced oxygen saturations. He has had mild asthma since childhood but no other medical history of note. His medications are a salbutamol inhaler when required and co-codamol for long standing back pain. On examination he is found to have an early diastolic murmur but no other abnormalities are detected. He goes on to have a chest x-ray which demonstrates apical interstitial shadowing. He undergoes pulmonary function tests which are as follows:

FEV1	1.9L	(Predicted 2.1-3.1)
FVC	2.2	(Predicted 3.0-4.4)
TLC	4.5	(Predicted 5.0-7.5)
Transfer factor (DLCO)	Low	

What is the most likely diagnosis?

	Ankylosing spondylitis
	Asbestosis
	Extrinsic allergic alveolitis
	Churg-Strauss syndrome
	Sarcoidosis

Question 69 of 200

□ □

A 58 year-old male presents with a 4 hour history of chest pain and breathlessness. The pain is right-sided and is sharp in nature, worsening on deep inspiration.

His medical background includes chronic obstructive airways disease. He has a 40-pack-year smoking history.

A recent respiratory clinic letter proves the following results from a spirometry test:

FVC	2.8L
FEV1	1.47 (40% predicted)
FEV1 / FVC ratio	53%

On examination he is tachypnoeic with a respiratory rate of 28. His oxygen saturations are 92% on room air.

An ECG reveals sinus tachycardia with a rate of 112 beats per minute.

A chest radiograph reveals a right-sided pneumothorax 1.8cm in width at the level of the hilum

What is the most appropriate initial management?

	Pleural aspiration
	High-flow oxygen
	Insert chest drain
	Talc pleurodesis
	Observe for 24 hours

Question 71 of 200

□ □

A 45-year-old male with long standing asthma presents to his specialist doctor complaining of recurrent chest infections over the last year. He has a productive cough most mornings of thick, brownish sputum for most days of the last year and he feels it is getting worse. He has been to his general practitioner on a number of occasions and been treated with oral antibiotics and steroids but with no significant impact on symptoms. His general practitioner has also stepped up his asthma treatment to regular use of a long-acting beta-2 adrenergic agonist and an inhaled steroid, which he feels may have made a slight difference. He denies any fevers or night sweats but has lost approximately two kilograms in weight over the last year. He was diagnosed with asthma as a teenager, takes his inhalers regularly and has never had any hospital admissions. He has no other medical conditions and takes no other medications other than over the counter vitamin supplements. He drinks a moderate amount of alcohol and does not smoke. He works as an economist and travels regularly to the middle east and china.

On examination, he is comfortable at rest. His respiratory rate is 16 breaths/min, his oxygen saturation 95% breathing room air and his chest is clear to auscultation. His heart rate is 65 beats/min and his heart sounds are normal. There is no palpable lymphadenopathy in the axillae or groin.

What is the most likely diagnosis?

	Cystic fibrosis
	Allergic broncho-pulmonary aspergillosis
	Tuberculosis
	Lung cancer
	Pseudomonas infection

Question 76 of 200

A 70-year-old lady with a background of type 2 diabetes mellitus and alcohol abuse presents with a fever and productive cough. She reports no weight loss or haemoptysis. She was born in England and has never travelled outside of the United Kingdom. She has never smoked cigarettes. On examination, she has crackles in her right upper lobe but is otherwise well and stable. A chest radiograph reveals consolidation which is cavitating in her right upper lobe. What is the most likely diagnosis?

	Lung cancer
	Tuberculosis
	Pneumococcal pneumonia
	Klebsiella pneumonia
	Aspergillosis

Question 77 of 200

□ □

A 75-year-old retired builder presents with a 2-month history of shortness of breath on exertion with associated chest pain, which he describes as a dull discomfort. The patient has no medical history of note and takes no regular medications. Up until his symptoms developed he was independent with all his activities of daily living.

Examination revealed decreased breath sounds on the right-hand side and a chest x-ray confirmed a right-sided pleural effusion with pleural thickening. A CT scan of the chest was then performed and the patient was referred to the thoracic surgeons for a video-assisted thoracoscopic surgical (VATS) biopsy to confirm the diagnosis.

What is the most appropriate management?

	Chemotherapy
	Chest drain insertion
	Pneumonectomy
	Radical radiotherapy
	Radiotherapy to surgical port sites

□ Question 78 of 200

□ □

A 45 year old patient undergoing R-CHOP (Rituximab, Cyclophosphamide, Doxyrubicin, Vincristine and Prednisolone) chemotherapy for Non-Hodgkins Lymphoma presents with a progressive cough, rigors and fevers up to 39.4 degrees on his home thermometer. His GP had tried 2 courses of antibiotics that had no beneficial effect on his symptoms. He attended to the Medical Assessment Unit after a particularly bad episode of coughing having experienced blood stained sputum.

Investigations are as follows

Hb	10.4 g/dl
Platelets	460 * 10 ⁹ /l
WBC	16.4 * 10 ⁹ /l
Neutrophils	13.5 * 10 ⁹ /l
Lymphocytes	2.7 * 10 ⁹ /l

Na ⁺	134 mmol/l
K ⁺	4.2 mmol/l
Urea	7.4 mmol/l
Creatinine	106 µmol/l

Chest X-Ray

- Cavitating lesion in the right upper zone.
- No evidence of pleural effusion
- No other focal consolidation

CT Thorax

- Cavitating lesion with halo sign

Broncho-alveolar lavage induced sputum

- Hyphae seen on silver staining

What is the most likely diagnosis?

	Invasive Aspergillosis
	Allergic Bronchopulmonary Aspergillosis
	Aspergilloma
	Tuberculosis
	Post atypical pneumonia lung abscess

Dashboard

Question 79 of 200

A 65-year-old female presents to respiratory outpatients with an 8-week history of gradually worsening shortness of breath. Her exercise tolerance has reduced to 50 yards from several miles; she reports chronic lower back pain but no other symptoms. Her past medical history includes type 2 diabetes mellitus, psoriasis, recurrent urinary tract infections and ischaemic heart disease. She currently takes metformin 500 mg BD, bisoprolol 2.5 mg OD, aspirin 75 mg OD, atorvastatin 40 mg ON, ramipril 2.5 mg and nitrofurantoin 50 mg ON with no change in the last 6 months. She has never smoked, has no pets and works as a secretary. On examination, the patient is breathless on minimal exertion. Observations are normal, there is no clubbing and she has fine end-inspiratory crepitations at both bases. A CT chest shows ground glass changes with minimal honey combing at both bases. What is the most likely cause of her underlying respiratory condition?

	Asbestosis
	Psoriasis
	Metformin
	Ankylosing spondylitis
	Nitrofurantoin

Question 83 of 200

A 30-year-old man was referred to his local hospital with a 7-day history of fever and dry cough. His General Practitioner had prescribed a course of amoxicillin but this had made no difference. Over the next few days the patient had got worse and developed a productive cough, diarrhoea and nausea. His girlfriend had also reported that the patient had been having rigors and had been confused. The patient smoked 15 cigarettes per day and drank approximately 30 units per week.

On examination he was confused and mildly jaundiced. Temperature was 39°C and respiratory rate was 30/min. Auscultation of the chest revealed scattered crackles in the right mid and lower zones. Abdominal and neurological examination was normal.

Investigations showed (normal values are shown in brackets):

Hb	10.4 g/dl
WCC	$10.6 \times 10^9/l$
Platelets	$180 \times 10^9/l$
Sodium	127 mmol/l
Potassium	3.6 mmol/l
Urea	7.0 mmol/l
Creatinine	115 mol/l
Bilirubin	44 μ mol/l
AST	200 iu/l
ALT	235 iu/l
Albumin	33 g/l

Arterial blood gases

pH	7.36 (7.35-7.45)
----	------------------

pO2	7.85 kPa (>10.6)
pCO2	5.6 kPa (4.7 -6)
HCO3	28 mmol/l (22-28)

Chest X-ray shows diffuse patchy shadowing in the right lung field

What is the most probable diagnosis?

	Chlamydia psittaci pneumonia
	Coxiella pneumonia
	Legionnaires disease

□ Question 84 of 200

□ □

As the doctor on call you are called to review a 28-year-old male on the haematology ward. He recently underwent an allogenic stem cell transplant, which so far had been reasonably uncomplicated. Earlier in the week the patient had complained of coryzal symptoms and a dry cough. A nasopharyngeal aspirate (NPA) had been sent along with other routine tests 24 hours ago.

When you arrive to review the patient on the ward you note that he appears extremely sweaty. You take his temperature using a tympanic thermometer which reads 39.5°C. His heart rate is 95 beats per minute and his respiratory rate is 16 breaths per minute. Blood pressure is 122/76 mmHg. Physical examination is unremarkable and chest X-ray reveals clear lung fields.

You review the patients most recent results:

Hb	95 g/l	Na ⁺	134 mmol/l
Platelets	50 * 10 ⁹ /l	K ⁺	3.6 mmol/l
WBC	0.1 * 10 ⁹ /l	Urea	3.0 mmol/l
Neuts	0.1 * 10 ⁹ /l	Creatinine	65 µmol/l
Lymphs	0.0 * 10 ⁹ /l	CRP	12 mg/l
Eosin	0.0 * 10 ⁹ /l		
NPA	Influenza A		

What is the most appropriate treatment to commence?

	Amoxicillin
	Oseltamivir
	No treatment required
	Flucloxacillin

	Zanamivir
--	-----------

□ Question 85 of 200

A 51-year-old lady is admitted to the Medical Admissions Unit with a 2-week history of fever, breathlessness, lethargy and fatigue.

She has a history of poorly controlled asthma which has caused her to attend the Emergency Department five times over the past 2 years. She was reviewed by the respiratory team during her last admission and started on reducing dose oral prednisolone. However, she was unable to reduce her dose below 10mg per day due to recurrent breathlessness and wheeze.

She was reviewed again in the Respiratory Clinic 4 months ago and started on montelukast 10mg per day as a steroid-sparing therapy. Her prednisolone was subsequently reduced to 5mg per day and she reports that she had been well since then.

Her past medical history is otherwise remarkable for sinusitis and nasal polyposis. She has had several surgeries for the latter. Her current medications include Seretide 500/50 1 puff twice daily, montelukast 10mg once daily, prednisolone 5mg once daily and salbutamol via MDI as required. She is allergic to aspirin.

On examination, her temperature is 37.6°C, her pulse is 98bpm and her blood pressure is 164/91mmHg. Her respiratory rate is 22/min and her oxygen saturations are 93% breathing room air. Her JVP is elevated at 5cm. Auscultation of the chest reveals diffuse polyphonic wheeze and bibasal crackles extending to the mid-zones. There is mild ankle oedema. Her abdomen is soft and non-tender.

Her initial investigations are as follows:

Hb	112 g/l	Na ⁺	136 mmol/l
Platelets	215 * 10 ⁹ /l	K ⁺	5.9 mmol/l
WBC	14.2 * 10 ⁹ /l	Urea	22.3 mmol/l
Neuts	8.4 * 10 ⁹ /l	Creatinine	484 µmol/l
Lymphs	2.1 * 10 ⁹ /l	CRP	107 mg/l
Eosin	3.4 * 10 ⁹ /l		

Urine dipstick | Blood + + + protein + +

What would be the most likely finding on renal biopsy?

	Mesangial hypercellularity
	Pauci-immune crescentic glomerulonephritis
	Podocyte fusion
	Thickened capillary walls with subepithelial deposits
	Diffuse proliferative glomerulonephritis

Dashboard

Overall score: **0%**

Question 85 of 200

A 51-year-old lady is admitted to hospital with cough and fatigue.

She has a history of poorly controlled asthma over the past 2 years. She was treated with inhaled corticosteroids and prednisolone. However, she has recently developed wheeze.

She was reviewed again in the outpatient clinic for tapering therapy. Her prednisolone was stopped since then.

Her past medical history is clear apart from asthma. Her current medications are inhaled corticosteroids 5mg once daily and salbutamol 2 puffs as required.

On examination, her temperature is 37.6°C, her pulse is 98bpm and her blood pressure is 164/91mmHg. Her respiratory rate is 22/min and her oxygen saturations are 93% breathing room air. Her JVP is elevated at 5cm. Auscultation of the chest reveals diffuse polyphonic wheeze and bibasal crackles extending to the mid-zones. There is mild ankle oedema. Her abdomen is soft and non-tender.

Her initial investigations are as follows:

Hb	112 g/l	Na ⁺	136 mmol/l
Platelets	215 * 10 ⁹ /l	K ⁺	5.9 mmol/l
WBC	14.2 * 10 ⁹ /l	Urea	22.3 mmol/l
Neuts	8.4 * 10 ⁹ /l	Creatinine	484 µmol/l
Lymphs	2.1 * 10 ⁹ /l	CRP	107 mg/l
Eosin	3.4 * 10 ⁹ /l		

Urine dipstick Blood + + + protein + +

What would be the most likely finding on renal biopsy?

	Mesangial hypercellularity
	Pauci-immune crescentic glomerulonephritis
	Podocyte fusion
	Thickened capillary walls with subepithelial deposits
	Diffuse proliferative glomerulonephritis

□ Question 86 of 200

□ □

A 64-year-old man presents to the respiratory clinic for review. He has been diagnosed with idiopathic pulmonary fibrosis which has not responded to a course of oral corticosteroids. He is finding it difficult to manage the stairs more than once per day and is finding it difficult to get out of the house. On examination his blood pressure is 138/88 mmHg, his pulse is 80 beats per minute and regular. There are inspiratory crackles on auscultation of the chest consistent with pulmonary fibrosis, and his O2 saturation is 92% at rest. His FVC is 65% of predicted. Which of the following is the next most appropriate intervention?

	Cyclophosphamide
	Infliximab
	Methotrexate
	Nintedanib
	Rituximab

Question 87 of 200

□ □

A 65-year-old man, originally from Pakistan is referred to the rapid access chest clinic by his GP with a one month history of weight loss (of roughly 5 kg) and a dry, irritating cough. Over the past two days he has started to have loss of sensation in both of his feet and lower legs.

Examination reveals heart sounds 1 and 2 present with no added sounds, reduced air entry in the mid and lower left zones of the chest, a non-tender liver edge that extends 3cm below the costal margin and loss of sensation for pain, light touch and temperature in both feet up to the mid shin.

A chest X-ray is performed which shows a unilateral hilar mass, but no other consolidation or features. His past medical history includes mild hypertension and diabetes mellitus which is diet-controlled. His only medication is enalapril for his hypertension. Bloods reveal no obvious abnormality.

What is the most likely diagnosis?

	Squamous cell carcinoma
	Small cell carcinoma
	Adenocarcinoma
	Tuberculosis
	Sarcoidosis

□ □

A 54-year-old gentleman is investigated following complaints of frothy urine. Investigations show proteinuria and mild kidney injury, but normal full blood count, liver function tests, inflammatory markers and an ultrasound scan of the kidneys. During examination, he found to have a systolic murmur on the left sternal edge. A transthoracic echocardiogram demonstrates a left ventricular ejection fraction of 55%, normal valves, and increased thickness of the left ventricle to 16mm. In addition, there is a 2mm pericardial effusion and ground-glass changes of the left ventricle. He has no chest pain or shortness of breath. What is the most likely explanation of these echocardiogram findings?

	Cor pulmonale
	Myocarditis
	Mitochondrial disease
	Type 2 diabetes mellitus
	Amyloidosis

Question 90 of 200

□ □

A 55-year-old man presented with history of progressive dyspnoea and dry cough for the past 3 years. In the past, he had exposure to asbestos when he worked in a chemical plant for 20 years, which he ceased 10 years ago. He was an ex-smoker with 40 pack years history. He quit smoking 2 years ago.

On examination, there were crackles in bilateral infrascapular area.

Computed tomogram (CT) of the chest showed honeycombing, thickening of interlobular and intralobular septa, diffuse pleural thickening, parenchymal bands, rounded atelectasis and calcified pleural plaques. Pulmonary function tests suggested restrictive ventilatory disease of moderate severity with moderate impairment of diffusion capacity.

What is the appropriate management for this case?

	Steroids
	Azathioprine
	Steroids plus azathioprine
	Anti-fibrotic agents
	Conservative management plus medical surveillance

□ Question 91 of 200

□ □

A 67-year-old gentleman presents to the respiratory clinic via the 2-week rule. He presented to his general practitioner with haemoptysis and a persistent cough. On examination in the clinic, you observe that his clothes are loosely fitted. Chest percussion reveals left upper zone dullness. Chest X-ray confirms the presence of a left upper zone mass. After discussion with your consultant an urgent staging Computerised Tomography (CT) is arranged which unfortunately confirms a large left upper zone mass, mediastinal lymph node involvement and hepatocellular metastases. His performance status is 1. Hyponatraemia is noted on the bloods you requested in the clinic.

Na ⁺	126 mmol/l
K ⁺	4.1 mmol/l
Urea	7.5 mmol/l
Creatinine	91 µmol/l

In the context of the most likely diagnosis and staging, what would be the most appropriate treatment option?

	Lobectomy
	Partial pneumonectomy
	Palliation
	Chemotherapy
	Radiotherapy

□ Question 95 of 200

□ □

A 17-year-old man is referred by the emergency department with weakness of his lower limbs and hands, worsening over the last 2 days. He is having increasing difficulty walking and is becoming very clumsy and dropping things. He burnt his hand yesterday in the kitchen without realising until afterwards that he had done it. He also complains of feeling dizzy on standing but has no chest pain or palpitations. He is normally fit and well, although did suffer a bout of diarrhoea and vomiting 4 weeks ago. He is on no regular medication and denies any alcohol or smoking history.

On examination he is afebrile, his blood pressure is 128/79 mmHg on lying but on standing it drops to 90/60 mmHg. His respiratory rate is 20/min and his saturations are 97% on air. His cardiovascular, respiratory and abdominal examinations are normal. Neurological examination reveals symmetrical distal weakness of his lower limbs with relative proximal sparing and altered sensation to fine touch, vibration and proprioception. He has similar findings in his upper limbs. He is suspected of having Guillain-Barre syndrome and following blood tests, CT head and lumbar puncture is started on IV immunoglobulins. Despite this, he begins to become increasingly short of breath and he is referred to ITU for respiratory support.

What respiratory parameter is used to determine if invasive ventilator support is needed?

	pO ₂ on ABG < 8kPa
	FEV ₁ :FVC ratio < 0.7
	Saturations on 15 litres O ₂ less than 93%
	FVC < 15ml/kg
	Peak flow of less than 300ml

Question 96 of 200

□ □

A 63-year-old is reviewed following admission with an infective exacerbation of COPD. He originally presented with shortness of breath, tight-chestedness and feeling generally unwell. He was initially managed with medical treatment including IV piperacillin with tazobactam, IV hydrocortisone, IV fluids, nebulised salbutamol and nebulised ipratropium bromide but his hypercapnia and acidosis failed to improve. He was then initiated on non-invasive ventilation (NIV) starting with IPAP of 10 cm H₂O and EPAP of 4 cm H₂O. He has managed to have the IPAP increased to 14 cm H₂O but he is struggling to tolerate this as he is feeling increasingly anxious. He has only had NIV for three hours so far.

Arterial blood gas results:

	On admission	Current
pH	7.11	7.23
pCO ₂	14.7	12.1
pO ₂	8.4	10.7

What is the most appropriate method to help him settle him?

	Give him haloperidol
	Give him diazepam
	Increase IPAP
	Decrease IPAP
	Stop NIV

Overall score: **0%**

Question 97 of 200

□ □

An 84-year-old gentleman with known metastatic lung cancer comes to the oncology clinic for review. He was treated with multiple courses of radiotherapy but with lack of response the treatment has stopped and he is being managed symptomatically. He has noticed that his face looks different and whilst not concerning him, his daughter wanted him to mention it.

On examination, he has drooping of the right eyelid and the right pupil is smaller. What other feature would be consistent with Horner's syndrome?

	Wasting of the small muscles of the hand
	Ipsilateral loss of sweating of the face
	Supraclavicular mass
	Inability to abduct the ipsilateral shoulder
	Shoulder pain

Question 98 of 200

A 24-year-old woman is admitted to Accident and Emergency with acute shortness of breath. She is unable to detail a clinical history due to shortness of breath. Her medication includes;

Cetirizine 10mg Orally Once Daily
Clobetasone butyrate (Eumovate) Topical

Her initial examination revealed bilateral widespread polyphonic wheezes. Her pulse rate was 102 beats per minute and blood pressure 128/75 mmHg. Her respiration rate was 33. Her oxygen saturations were 96% on 4L/min via face mask. She had a dry flaking rash in her elbow flexures with signs of excoriation.

The following blood tests were obtained;

Hb	11.2 g/dl
Platelets	$204 \times 10^9/l$
WBC	$10.3 \times 10^9/l$
Eosinophil	$0.56 \times 10^9/l$
CRP	65
Na+	135 mmol/l
K+	4.4 mmol/l
Urea	7.6 mmol/l
Creatinine	101 μ mol/l

Chest x-ray was clear. A peak expiratory flow was 200 L/min(expected 402).

Initial arterial blood gas on 4L/min oxygen via face mask;

pH	7.46

pCO2	3.5 kPa
pO2	14 kPa
HCO3	19 mmol/l
Lactate	1.8 mmol/l

She is treated with nebulised salbutamol and ipratropium bromide and oral prednisolone 40mg and oxygen 4L/min.

You re-review the patient 30 minutes later on the Admissions Unit. Her examination reveals symmetrical quiet breath sounds and quiet bilateral wheezes. She has symmetrical chest wall movement. Her pulse rate is 80 beats per minute. Blood pressure 103/68 mmHg. Her respiratory was 18 with oxygen saturations 94% on 6L/min via face mask. Peak expiratory flow was 120 L/min.

Repeat arterial blood gas on 6L/min oxygen via face mask;

pH	7.33
pCO2	6.2kPa
pO2	13kPa
HCO3	20 mmol/l
Lactate	2.2 mmol/l

What is the most appropriate treatment?

<input type="checkbox"/>	Intravenous Magnesium
<input type="checkbox"/>	Reduce oxygen levels
<input type="checkbox"/>	Intravenous Salbutamol
<input type="checkbox"/>	Referral to intensive care
<input type="checkbox"/>	Biphasic positive airway pressure

Question 98 of 200

A 24-year-old woman is admitted to Accident and Emergency with acute shortness of breath. She is unable to detail a clinical history due to shortness of breath. Her medication includes;

Cetirizine 10mg Orally Once Daily
Clobetasone butyrate (Eumovate) Topical

Her initial examination revealed bilateral widespread polyphonic wheezes. Her pulse rate was 102 beats per minute and blood pressure 128/75 mmHg. Her respiration rate was 33. Her oxygen saturations were 96% on 4L/min via face mask. She had a dry flaking rash in her elbow flexures with signs of excoriation.

The following blood tests were obtained;

Hb	11.2 g/dl
Platelets	$204 \times 10^9/l$
WBC	$10.3 \times 10^9/l$
Eosinophil	$0.56 \times 10^9/l$
CRP	65
Na+	135 mmol/l
K+	4.4 mmol/l
Urea	7.6 mmol/l
Creatinine	101 μ mol/l

□ Question 99 of 200

□ □

A 35 year old chronic alcoholic male is admitted with severe epigastric pain. Laboratory investigations confirmed a significantly raised amylase. He is started on treatment for severe pancreatitis but his condition deteriorated over the next 2 days and he developed acute kidney injury with severe respiratory distress to an extent needing mechanical ventilation. Initial chest radiographs revealed widespread bilateral infiltrates. Which of the following therapies has been shown to most likely decrease overall mortality of ARDS?

	Immediate initiation of glucocorticoid therapy to limit inflammatory progression
	Placing patient in the prone position, allowing for greater recruitment of unaffected alveoli and improving PaO ₂ /FiO ₂ ratio
	Implementing a low tidal volume ventilation protocol
	Changing from O ₂ to Nitric oxide at 5 ppm and titrating up until pt has an acceptable PaO ₂ /FiO ₂ ratio
	Aggressive diuresis to reduce pulmonary edema and vascular congestion

Dashboard

Question 100 of 200

A 50-year-old woman was referred to the clinic with a 6-month history of shortness of breath. She gave a history of progressive exertional breathlessness and now could only walk a couple of hundred meters. In addition she also noted swelling of her ankles that started 3 weeks ago and had experienced 1 episodes of loss of consciousness. She had been a wheezy child but had grown out of it. She was a non-smoker and drank approximately 5 units of alcohol per week. She took no regular medications and had no known allergies. Her General Practitioner had prescribed salbutamol and beclomethasone inhalers for her but this had made no difference.

On examination her heart rate was 86 beats per minute, blood pressure 135/90 mmHg, respiratory rate 20 breaths per minute and oxygen saturations were 93% on room air.

Initial investigations are shown below:

Full blood count, urea and electrolytes, liver function tests: normal
Autoantibody screen: negative

Chest x-ray: clear lung fields, no cardiomegaly

Lung function tests:
-forced expiratory volume in 1-second 2.8L (115% predicted)
-forced vital capacity 3.2L (120% predicted)
-total lung capacity 5.8L (120% predicted)
-carbon monoxide diffusion in the lungs 92%

Transthoracic echocardiogram:
-left ventricle: normal size, ejection fraction 65% (>55)
-normal aortic and pulmonary valves
-right ventricle dilated
-tricuspid regurgitation (mild)
-pulmonary artery systolic pressure: 55 mmHg

CT scan on chest: normal

Ventilation-perfusion (V/Q) scan: low probability for thromboembolic disease

What is the appropriate next investigation?

	Bronchoscopy and bronchoalveolar lavage
	Cardiac catheterisation
	CT guided lung biopsy
	CT pulmonary angiography
	Genetic testing for cystic fibrosis

Dashboard

Question 101 of 200

□ □

A 30-year-old pregnant woman (24 weeks) is admitted to the acute medical unit with sudden onset shortness of breath and pleuritic chest pain. She has no past medical history other than eczema and this is her first pregnancy.

On examination, auscultation of her chest reveals only a mild wheeze with oxygen saturations of 94% on room air and a respiratory rate of 25/min. Her heart sounds are normal, with a heart rate of 97bpm and blood pressure is 105/60 mmHg. An ECG shows sinus rhythm.

The FY1 doctor on the ward has requested a D-dimer to try and 'speed up the diagnosis', which comes back positive.

What is the next appropriate investigation?

	Ventilation-Perfusion (V/Q) scan
	Chest x-ray
	Peak flow measurement
	CT Pulmonary Angiogram (CTPA)
	Ultrasound doppler of the lower legs

Dashboard

Overall score: 0%

Question 102 of 200

□ □

A 20-year-old woman presents to her general practitioner with persistent episodic shortness of breath and a dry cough. She is currently being treated by her GP for asthma and takes 2 puffs of Seretide 25/100 (salmeterol and fluticasone) twice a day using a metered dose inhaler with a spacer, which control her symptoms for the majority of the day - however she still gets wheezy and short of breath upon running or cycling. Her only other past medical history of note includes allergic rhinitis for which she takes loratadine and has been on a number of different nasal sprays for.

Examination of the chest was normal and peak expiratory flow readings were 78% predicted.

What is the most appropriate next step in this case?

	Add in oral theophylline
	Add in an oral leukotriene antagonist
	Increase the long-acting beta antagonist
	Add in a long-acting muscarinic antagonist
	Add in an oral steroid

Dashboard

Question 103 of 200

□ □

A 72 year-old woman has been referred to the chest clinic by her General Practitioner (GP). The patient describes a 3-year history of cough and progressive shortness of breath. Over the past 3 years the GP had prescribed numerous courses of antibiotics and steroids but these had had little benefit. She was a non-smoker, did not drink alcohol and was on no regular medications. The cough was productive of purulent sputum with occasional streaks of blood. There was no history of weight loss or fever, but the patient did note lethargy. The rest of her family were well and the only medical history of note was an episode of pneumonia as a child.

Respiratory examination revealed bilateral crackles but no other added sounds. You note that the patient was not clubbed.

A chest x-ray, organised by the GP, shows minor bilateral atelectasis and opacities.

What is the most appropriate diagnostic test?

	Bronchoscopy
	Genetic testing for Primary Ciliary Dyskinesia
	High resolution CT scan of chest
	Serum α 1-antitrypsin level
	Tuberculin skin test

Dashboard

Question 109 of 200

A 35-year-old man presents with a chronic productive cough which has been affecting him for several years. He has no other past medical history apart from recurrent otitis media as a child. He takes no regular medications. He has never smoked and has no history of passive smoking and works as a solicitor. He has no pets at home and has no mould that he is aware of. On examination there is finger clubbing, he appears underweight, there are coarse late-inspiratory crepitations and a mild wheeze. Also, his heart sounds are louder on the right side, and his apex beat is also only present on the right. What further investigation would most likely confirm the diagnosis?

	Immunological testing for <i>Aspergillus fumigatus</i> specific IgE
	CFTR gene testing
	Sputum MCS
	Sputum Zeil-Neilsen staining and microscopy.
	Ciliary function tests

Question 110 of 200

A 23-year-old female student presents to the emergency department with a headache which has developed since starting her third year at university studying economics. She has also been noticing nausea and breathlessness. She had spent the summer travelling to Argentina and teaching English, after which she returned to the UK and moved into shared student accommodation in preparation for her next term. She had been well during her travels except for four days of diarrhoea shortly after she arrived. She has a past medical history of chlamydia which was treated by a local GUM clinic. She does not smoke and has minimal alcohol intake. On examination, she appears tired but otherwise well. Auscultation of her chest is normal. A urinary pregnancy test is positive.

Blood tests:

Hb	127 g/l
Platelets	336 * 10 ⁹ /l
WBC	9.4 * 10 ⁹ /l
Na ⁺	137 mmol/l
K ⁺	4.2 mmol/l
Urea	3.7 mmol/l
Creatinine	63 µmol/l

Arterial blood gas:

pH	7.41 g/l
pCO ₂	3.6 mmHg
pO ₂	9.4 mmHg
Na ⁺	137 mmol/l
FCOHb	22%

She is started on 15L of oxygen via a non-rebreather mask. How should she be further managed?

	Wean off oxygen guided by standard pulse oximetry saturation levels
	Add IV mannitol
	Maintain high-flow oxygen until asymptomatic or carbon monoxide levels are <10%
	Refer urgently for hyperbaric oxygen treatment
	Arrange urgently for non-invasive ventilation

Dashboard

Overall score: 0%

Creatinine	63 μ mol/l

Arterial blood gas:

pH	7.41 g/l
pCO ₂	3.6 mmHg
pO ₂	9.4 mmHg
Na ⁺	137 mmol/l
FCOHb	22%

She is started on 15L of oxygen via a non-rebreather mask. How should she be further managed?

	Wean off oxygen guided by standard pulse oximetry saturation levels
	Add IV mannitol
	Maintain high-flow oxygen until asymptomatic or carbon monoxide levels are <10%
	Refer urgently for hyperbaric oxygen treatment
	Arrange urgently for non-invasive ventilation

Question 111 of 200

□ □

A 50-year-old man presents with non-productive cough and breathlessness on exertion. He is feverish and has lost 6kg in 2 months. He has mild asthma but doesn't require medication. He is a non smoker.

Chest X-ray: peripheral lung infiltrates.

Hb	13.4 g/dl
Platelets	170 * 10 ⁹ /l
WBC	11.4 * 10 ⁹ /l (40% polymorphs, 16% lymphocytes)
CRP	13 mg/L
ESR	35 mm/h

What is the most likely diagnosis?

	Idiopathic pulmonary fibrosis
	Histiocytosis X
	Chronic eosinophilic pneumonia
	Lymphangioleiomyomatosis
	Löffler's syndrome

□ Question 112 of 200

A 67-year-old man comes to the emergency department with a severe unremitting headache which he says has built up steadily over the past week. He has had a chronic cough for the past 6 months and continues to smoke 30 cigarettes per day. On examination his blood pressure is 182/90 mmHg, his pulse is 90 beats per minute and regular. He has plethoric facies and you note dilated veins across his head, neck and arms. There is bilateral wheeze on auscultation of the chest.

Investigations

Hb	113 g/l
Platelets	$341 \times 10^9/l$
WBC	$8.2 \times 10^9/l$

Na ⁺	142 mmol/l
K ⁺	4.4 mmol/l
Urea	6.7 mmol/l
Creatinine	121 μ mol/l
Calcium	2.92 mmol/l

Chest x-ray - Right hilar mass consistent with bronchial carcinoma

Which of the following therapies is most appropriate for relieving his symptoms?

	Chemotherapy
	Prednisolone
	Radiotherapy

	Surgical bypass
	Venous stenting

Question 116 of 200

□ □

As the medical registrar on-call you are called to see a 25-year-old male in the Emergency Department (ED). The young male presented to the ED with a fever and productive cough of green sputum. When you arrive he looks unwell and although alert is a difficult historian.

Concerned, you immediately assess him from head to toe:

Airway	Airway patient, able to speak in sentences
Breathing	Sats 90% on room air, Resp Rate 25 / min, coarse creps bilaterally on auscultation
Circulation	Heart rate 110 beats per minute, blood pressure 90/55 mm/Hg
Disability	Glasgow coma scale 15/15, capillary blood glucose 5.5
Exposure	Multiple boils noted distributed widely across the patient's body

You inquire about the history of the boils identified on examination. The patient is unsure how long he has had them for, however, mentions that two of his family members recently were prescribed antibiotics by their family GP for similar lesions.

You start the patient on high flow oxygen, gain IV access taking blood cultures and give a fluid bolus. An urgent portable chest X-ray is requested which appears to show bilateral consolidation with multiple cavitating lesions.

What is the most likely diagnosis

	Streptococcal infection
	PVL-producing staphylococcal infection
	Tuberculosis
	Fungal chest infection
	Klebsiella infection

Question 117 of 200

□ □

A 71-year-old gentleman presented to the emergency department with a headache, myalgia and fever. These symptoms all started one day ago. He has a past medical history of hypertension, ischaemic heart disease, type 2 diabetes, congestive cardiac failure and bilateral hip replacement. His medications include amlodipine, ramipril, aspirin, atorvastatin, gliclazide, calcium carbonate with colecalciferol (Adcal-D3) and paracetamol. He denies any allergies. He is concerned that he about influenza as he visited a friend in hospital last week who had been diagnosed with influenza A.

On examination, he appears sweaty and feels hot to touch. His chest is clear on auscultation. He is placed in a side room for observation and viral throat swabs are requested.

Observations:

Oxygen saturation	96% on room air
Respiratory rate	18/min
Blood pressure	129/93mmHg
Heart rate	77/min
Temperature	38.1°C

What is the most appropriate treatment?

	Supportive management only
	Salbutamol
	Zanamivir
	Amantadine
	Oseltamivir

Question 119 of 200

□ □

A 57-year-old male is seen in the respiratory clinic with a three months history of a productive cough, weight loss and drenching night sweats. He reports that he is producing approximately 1 cup of green sputum each day and has lost 4 kgs during the same time period. He has smoked 20 cigarettes a day since he was 15 years old. He last traveled abroad 2 years ago, visiting family in North America.

The GP has performed routine blood tests which are unremarkable and a HIV test is negative. Several sputum samples have been sent for routine microscopy, culture & sensitivities (MC&S) growing only normal respiratory flora. Following a normal chest X-ray, you perform a high resolution CT (HRCT) scan. This demonstrates right middle lobe and left lower lobe bronchiectasis with multiple nodules in both lungs.

What other initial investigation would you perform to help reach a diagnosis?

	Sweat test
	PET-CT Scan
	Repeat HRCT scan in 3-6 months
	Sputum for acid fast bacilli (AFB)
	Bronchoscopy +/- biopsies

Question 121 of 200

□ □

A 46-year-old woman is reviewed prior to discharge due to abnormal findings on a CT pulmonary angiogram (CTPA). She had originally presented with chest pain. Her past medical history only included fractures of the tibia and fibula whilst intoxicated two weeks ago. She has no family history of cancer, and she does not smoke. She works as a teacher. On admission, she had sinus tachycardia, but this has settled, as has the chest pain. She had no abnormalities on examination, and it was noted that she was wearing a below knee plaster of Paris.

An ECG demonstrated sinus tachycardia on admission with a rate of 108/min. She underwent a CTPA which demonstrated no pulmonary embolism but incidentally detected a 4mm solid pulmonary nodule. She is due to be discharged as the chest pain has settled. How should the pulmonary nodule be investigated or monitored?

	Urgent image-guided biopsy
	Urgent CT-PET
	CT chest in three months
	CT chest in one year
	No further investigations or monitoring needed

□ Question 122 of 200

A 69-year-old man with a history of rheumatoid arthritis well controlled on methotrexate presents with gradual pain and swelling in his wrists and ankles.

The pain is described as a dull ache that is intermittent, often worse in the evenings. There is associated swelling which can sometimes feel warm. He has tried regular paracetamol but this has had limited effect.

He also describes a chronic cough and shortness of breath on exertion for the past 6 months that he has not mentioned to his GP. There has been no haemoptysis and he denies any fevers. His wife has noticed that he has been losing weight recently.

He has a past medical history of rheumatoid arthritis, hypertension, hypercholesterolaemia and type 2 diabetes mellitus. He currently takes methotrexate weekly, folic acid 5mg weekly, ramipril 5mg, simvastatin 20mg at night, metformin 500mg three times a day and paracetamol 1g four times daily.

He is a retired accountant and a current smoker with a 50 pack year smoking history. He drinks approximately 30 units of beer a week. He denies any recent foreign travel.

On examination, he is cachectic and short of breath on exertion. His pulse is 80/min and regular, blood pressure 140/93 mmHg, oxygen saturations of 93% on air. He has marked fingernail clubbing. Examination of his wrists reveals slightly swollen and tender joints. Swan neck and ulnar deviation deformities are noted in both hands. Other than his wrists, no other joint abnormalities are detected. Examination of the peripheral nervous system is normal.

Examination of his chest is normal with no focal consolidation.

Initial bloods are as follows:

Na ⁺	134 mmol/L
K ⁺	3.9 mmol/L
Urea	7.8 mmol/L
Creatinine	105 µmol/L
Hb	100 g/L

WBC	6.0x10 ⁹ /L
Platelets	200x10 ⁹ /L
LFTs	Normal
Serum uric acid	410 µmol/L
CRP	12 mg/L

Chest X-ray reveals a discrete opacification at the periphery of the right middle lobe.

What is the most likely underlying diagnosis?

	Methotrexate induced pulmonary fibrosis
	Bronchogenic carcinoma
	Caplan's syndrome
	Chronic obstructive pulmonary disease
	Pneumonia

Question 124 of 200

□ □

A 52-year-old woman presents to the respiratory clinic with breathlessness. She was referred from her GP who was concerned about breathlessness and a chest X-ray demonstrating left pleural effusion. She had recently undergone a left-sided wide local excision with axillary clearance for ductal carcinoma in situ.

She has unilaterally reduced breath sounds with dullness on percussion and deviation of the trachea away from that side of her chest. A plural aspirate is obtained and is milky white in colour. The two possibilities considered are chylothorax from pseudochylothorax.

What investigation would aid in distinguishing chylothorax from pseudochylothorax?

	pH
	Albumin
	Microscopy
	Triglycerides
	Amylase

Question 125 of 200

□ □

A 64-year-old woman presents to the emergency department with breathlessness. She has been feeling progressively breathless over the last two weeks with marked reduction in her exercise tolerance. She now finds that even a few steps make her short of breath whilst normally she would be able to walk to her local shops and back. She finds that she cannot lie down as it makes her feel worse. She has a past medical history of hypertension, previous myocardial infarction and asthma.

On examination, she has a raised JVP, bilateral crepitations on auscultation, reduced air entry in both bases and dull percussion. On her chest X-ray, there is evidence of pulmonary oedema and bilateral pleural effusions. What is the most appropriate management plan?

	Treat medically with diuretics
	Pleural aspirate and if exudate insert chest drain
	Insert chest drain on one side
	Insert chest drain on both sides
	Non-invasive ventilation

□ Question 126 of 200

A 17-year-old male is admitted to the resuscitation area of the emergency department with an acute exacerbation of asthma. It is his 3rd hospital attendance this winter. He has widespread wheeze, globally poor air entry and looks tired. He cannot complete full sentences. His arterial blood gases reveal:

pH	7.4
PaO ₂	9.3 kPa
PaCO ₂	3.3 kPa
HCO ₃ ⁻	26 mmol/L

You treat him with 100% oxygen, high dose steroids, back to back salbutamol nebulisers and commence intravenous magnesium sulphate infusion. 1 hour later his arterial blood gases reveal:

pH	7.35
PaO ₂	15.4 kPa
PaCO ₂	4.7 kPa
HCO ₃ ⁻	22 mmol/L

What is the next management step?

	Start BIPAP
	Intensive care review
	Move to medical ward with close monitoring
	Intravenous adrenaline
	Start CPAP

Dashboard

Question 130 of 200

A 67-year-old gentleman presents with a three-day history of a productive cough. He complains that over the last two days he has been progressively more short of breath, He complains of feeling very weak and lethargic and on further questioning reports fevers and rigors. His wife brought him to the emergency department as she was concerned as he appeared to be deteriorating rapidly.

Observations are: heart rate 125 beats per minute, respiratory rate 32 breaths per minute, S_aO_2 90% on room air, temperature 38.9°, blood pressure is 130/84 mmHg.

He appears distressed but is not confused.

Initial investigations show:

Hb	134 g/l
Platelets	$550 \times 10^9/l$
WBC	$18 \times 10^9/l$

Na^+	141 mmol/l
K^+	3.7 mmol/l
Urea	9.2 mmol/l
Creatinine	130 μ mol/l

Chest x-ray shows left lower zone consolidation.

From the above information, what is his CURB-65 score?

Question 131 of 200

□ □

A 32-year-old man has a long history of asthma and over the last eight weeks, he has been needing to use his salbutamol inhaler four times per week in order to manage asthma symptoms. Prior to this, he was also waking up once per night due to the symptoms but since the introduction of a long-acting beta 2 agonist in combination to the regular two puffs twice a day of 100 micrograms beclometasone that he takes the nighttime symptoms have resolved. He has good inhaler technique and is compliant with medications. He works in sales and has never had any identifiable environmental triggers for his asthma. What is the next best step in his management?

	Keep him on the same medications and review him again in 3 months time
	Change beclometasone to 200 micrograms taken two puffs twice a day
	Add in leukotriene receptor antagonist
	Add in tiotropium 18 micrograms once daily
	Add in sustained-release (SR) theophylline

□ Question 137 of 200

A 72-year-old man was admitted to hospital with an exacerbation of his longstanding chronic obstructive airways disease. The patient's regular treatment for COPD included home oxygen, home bronchodilator nebulisers and high-dose inhaled steroids. Normal exercise tolerance was very limited with the patient becoming profoundly breathless after mobilising only short distances around his house. Following an admission to the intensive care unit for respiratory support the previous winter the patient had expressed a wish that he would not want non-invasive ventilation or intubation in the future and stated that control of his symptoms was his priority.

Treatment with prednisolone, nebulised bronchodilators and antibiotics was started on admission. Having been profoundly dyspnoeic at rest at admission the patient's symptoms improved gradually over the next week until the patient returned to his baseline of dyspnoea on minimal physical exertion. He again requests if there is any other treatments that can ameliorate his symptoms.

Recent investigations are summarised below.

Forced vital capacity: 115 % predicted
Forced expiratory volume (1s): 34 % predicted
FEV1 / FVC: 30 % predicted

Haemoglobin	170 g / dL
White cell count	15.8 * 10 ⁹ /l
Platelets	167 * 10 ⁹ /l
Urea	6.7 mmol / L
Creatinine	98 micromol / L
Sodium	140 mmol / L
Potassium	4.1 mmol / L
Packed cell volume	0.42

What treatment is the best choice for relief of dyspnoea in this patient?

	Morphine sulphate modified release 10 mg twice daily
	Venesection
	Diazepam 2 mg four times daily
	Temazepam 10 mg at night
	Morphine sulphate liquid preparation 20 mg four times daily

Dashboard

□ Question 138 of 200

A 50-year-old man, presented with progressive shortness of breath and occasional dry cough of 4 weeks duration. He had underlying type 2 diabetes mellitus, hypertension and rheumatoid arthritis. He was a smoker with a smoking history of 15 pack years and a social drinker. His medications included metformin, enalapril and methotrexate which was started 6 weeks back along with folic acid supplementation.

On examination, his pulse rate was 100/min, blood pressure was 140/90 mmHg, respiratory rate was 20/min and was saturating 94% in room air. His chest revealed bibasal crackles on auscultation.

His blood counts were as follows-

Hb	150 g/l
Platelets	$150 \times 10^9/l$
WBC	$10 \times 10^9/l$
Eosinophils	$0.7 \times 10^9/sup/l$

CT chest showed patchy bilateral ground glassing with septal lines and few patchy consolidative changes.

What will be the appropriate next management?

	Cease methotrexate and start prednisolone 1mg/kg,
	Continue current treatment and add azithromycin
	Cease methotrexate and increase the dose of folic acid
	Cease methotrexate and evaluate for infections and cardiac failure
	Lung biopsy

□ Question 138 of 200

A 50-year-old man, presented with progressive shortness of breath and occasional dry cough of 4 weeks duration. He had underlying type 2 diabetes mellitus, hypertension and rheumatoid arthritis. He was a smoker with a smoking history of 15 pack years and a social drinker. His medications included metformin, enalapril and methotrexate which was started 6 weeks back along with folic acid supplementation.

On examination, his pulse rate was 100/min, blood pressure was 140/90 mmHg, respiratory rate was 20/min and was saturating 94% in room air. His chest revealed bibasal crackles on auscultation.

His blood counts were as follows-

Hb	150 g/l
Platelets	$150 \times 10^9/l$
WBC	$10 \times 10^9/l$
Eosinophils	$0.7 \times 10^9/sup/l$

CT chest showed patchy bilateral ground glassing with septal lines and few patchy consolidative changes.

What will be the appropriate next management?

	Cease methotrexate and start prednisolone 1mg/kg,
	Continue current treatment and add azithromycin
	Cease methotrexate and increase the dose of folic acid
	Cease methotrexate and evaluate for infections and cardiac failure
	Lung biopsy

Overall score: **0%**

□ Question 139 of 200

□ □

A 30 year old gentleman returns from a camping holiday in the Nile Delta with nocturnal wheeziness and dry cough, weight loss, and fever. He recalls multiple mosquito bites. Chest X-ray demonstrates pulmonary infiltrates. His blood results are shown below.

Hb	14 g/dl
Platelets	$385 \times 10^9/l$
WBC	$14 \times 10^9/l$
Neutrophils	$7.5 \times 10^9/l$ (reference range $2.0-7.5 \times 10^9/l$)
Eosinophils	$1.2 \times 10^9/l$ (reference range $0.04-0.44 \times 10^9/l$)

Serum IgG	90 mg/dl (reference range 80 - 350 mg/dl)
Serum IgM	200 mg/dl (reference range 45 - 250 mg/dl)
Serum IgE	6.0 mg/dl (reference range 0.002 - 0.2 mg/dl)

Given the likely diagnosis which of the following treatments will be most effective?

	Antiretrovirals
	Tazocin
	Steroids
	Diethylcarbamazine
	Quinine

Overall score: **0%**

Question 140 of 200

□ □

A 55-year-old man presents to the Emergency Department with sudden onset chest pain and associated shortness of breath. The chest pain is on the left hand side only and there is no history of cough, fever chills or recent fatigue. The patient is an ex-smoker and has a background of well-controlled chronic obstructive pulmonary disease (COPD).

On examination the patient is tachycardiac and tachypnoeic but otherwise the examination is normal.

Routine haematology and biochemistry are unremarkable but a chest x-ray shows a left sided pneumothorax which is measured to be approximately 2.5 cms.

Of the following options which represents the best management option?

	Admit the patient and observe with high flow oxygen
	Attempt aspiration using a 16-18G cannula
	Consider discharge and review the patient as an out-patient
	Insert a 8-14Fr chest drain and admit
	Intubation and ventilation

Dashboard

Question 141 of 200

□ □

A 67-year-old man presents to the emergency department with severe shortness of breath. He has a past medical history of COPD, type 2 diabetes mellitus and hypertension. On examination he appears very breathless and looks drowsy, with bilateral crackles and wheeze audible on auscultation. Following treatment with nebulisers, steroids, antibiotics and fluids he remains in type 2 respiratory failure with acidosis.

Arterial blood gas on admission:

pH	7.32
pO ₂	7.3kPa
pCO ₂	8.1kPa
HCO ₃ ⁻	25mmol/L

Arterial blood gas at two hours:

pH	7.30
pO ₂	8.2kPa
pCO ₂	9.6kPa
HCO ₃ ⁻	26mmol/L

He is started on non-invasive ventilation with a bi-level positive airway pressure. What initial settings would be most appropriate for IPAP and EPAP?

	IPAP 3cmH ₂ O and EPAP 15cmH ₂ O
	IPAP 10cmH ₂ O and EPAP 10cmH ₂ O
	IPAP 15cmH ₂ O and EPAP 3cmH ₂ O

Question 143 of 200

□ □

A 50-year-old man presents to his GP complaining of daytime somnolence. He reports that yesterday he fell asleep while stopped at a red light. His wife adds that he is a habitual snorer, and sometimes seems to stop breathing for seconds at a time while sleeping. His past medical history is significant for hypertension, a 25 pack-year smoking history, and a two beer per day drinking habit.

Physical examination reveals an obese, middle-aged man in no apparent distress. His pulse is 88/min, blood pressure is 160/100 mmHg, and respirations are 14/min. The remainder of the physical examination, including chest auscultation, is within normal limits.

Which of the following is the most appropriate next step in the management of this patient?

	Prescribe methylphenidate
	Pulmonary function testing
	MRI of the upper airways
	Nocturnal polysomnography
	Dexamethasone suppression test

Dashboard

A 45-year-old man is referred to the respiratory department due to increasing shortness-of-breath and frequent chest infections. He is a smoker (20 cigarettes/day). When he was a child he used a salbutamol inhaler but stopped this around the age of 6-7 years. He also had whooping cough as a child. Pulmonary function tests performed by his GP show the following:

FEV1	3.6 L (predicted 3.8 L)
FVC	4.3 L (predicted 4.5 L)
FEV1/FVC	84% (normal > 75%)

On auscultation of his chest scattered crepitations are noted. His oxygen saturations are 96% on room air.

A CT chest is requested:

□ □

A 32-year-old taxi driver attends the emergency department with pleuritic right-sided chest pain. He is a current smoker of 15 cigarettes/day. He reports feeling unwell for 10 days with a cough and fever. The chest pain started gradually over the last 2 days becoming slowly more severe. A chest x-ray shows right sided consolidation and an effusion. He is commenced on penicillin antibiotics. Pleural aspirate under ultrasound guidance shows a simple effusion and the following results:

Appearance	Serous
pH	7.30
Protein	46 g/l
LDH	400 IU/l
Glucose	3.7mmol/l
Gram stain	No organisms or malignant cells seen
Culture	No growth

What is the next best step?

	Intercostal drain
	Continue antibiotics and observe
	CT thorax with contrast
	Repeat pleural aspirate in 24 hours
	Further investigation with bronchoscopy

Overall score: **0%**

Question 151 of 200

□ □

A 25-year-old man presents to the emergency department complaining of breathlessness and pleuritic chest pain, which started suddenly 12 hours ago. He has no relevant past medical history, and is a non-smoker. His chest x-ray shows a pneumothorax with a 2cm rim. What is the correct management in this situation?

	Oxygen therapy to maintain saturations >95%
	Chest drain
	Aspiration
	Discharge with an outpatient review in 2 weeks
	Admit for observation

□ Question 152 of 200

□ □

A 23-year-old man presents with dyspnoea and haemoptysis to the Emergency Department. He initially thought his symptoms were due to a chest infection but a course of amoxicillin from his GP has not helped. He now feels short of breath on mild exertion and has coughed up fresh blood on a number of occasions today.

On examination his oxygen saturations are 92% on air. On examination he has crackles predominately in the upper and lower zones of the left lung. Temperature is 37.7°C.

Hb	13.1 g/dL
WCC	11.3 *10 ⁹ /l
Sodium	137 mmol/l
Potassium	4.2 mmol/l
Urea	6.4 mmol/l
Creatinine	123 µmol/l
CRP	188 mg/L

Urine dip: blood +++, leucocytes +

A chest x-ray is requested:

© Image used on license from Radiopaedia

Later tests during his admission show the following;

c-ANCA	Positive
p-ANCA	Positive
Anti-GBM	Negative

What is the most likely diagnosis?

	Granulomatosis with polyangiitis
	Cryptogenic organizing pneumonia
	Churg-Strauss syndrome
	Tuberculosis
	Goodpasture's disease

Question 153 of 200

□ □

A 72-year-old man is being treated on the ward for a severe infective exacerbation of COPD. On the ward round you notice he is more drowsy than usual. He is receiving intravenous antibiotics and nebulised salbutamol, driven by oxygen at 10 litres/minute. He requested the nebuliser as it relieves the distressing breathlessness he develops during exacerbations.

On examination his heart rate is 90 beats per minute, blood pressure is 140/80 mmHg and respiratory rate is 19 breaths per minute, oxygen saturations are 98%.

Arterial blood gas:

pH	7.27 (7.35-7.45)
PaO ₂	18.0 KPa (11.3-12.6)
PCO ₂	9 kPa (4.7-6.0)
Bicarbonate	30 mmol/L (21-29)

What is the most appropriate management?

	Add nebulised ipratropium bromide and re-check ABG
	Intravenous aminophylline and re-check ABG
	Stop oxygen immediately and re-check ABG
	Start non-invasive ventilation and re-check ABG
	Gradually step down oxygen to compressed air and re-check ABG

□ Question 155 of 200

A 66-year-old gentleman presented with a 4 day history of cough associated with green sputum. He has also been feeling more breathless, wheezy, feverish at times and having some right sided pleuritic chest pains. His past medical history includes chronic obstructive pulmonary disease, hypertension and diabetes. He has a 40 pack year history of smoking but he stopped 3 years ago.

On examination, he looks unwell, flushed and breathless at rest. His heart sounds are normal and he has right basal crackles with bronchial breathing and wheeze. There is no leg oedema or tenderness. His vital signs show pulse of 120 beats per minute, blood pressure of 120/70 mmHg, SaO₂ = 89% on 24% oxygen, respiratory rate of 32 breaths per minute and T=38.5°C.

His Electrocardiogram reveals sinus tachycardia and the chest X-ray confirms right basal consolidation.

The following bloods tests have been obtained:

Hb	13.1 g/dl
Platelets	180 * 10 ⁹ /l
WBC	15.4 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	4.9 mmol/l
Urea	10 mmol/l
Creatinine	120 µmol/l
CRP	180 mg/l

pH	7.28
pCO ₂	5.0 kPa
pO ₂	8.5 kPa

HCO3-	15 mEq/l
-------	----------

What is the best management?

	Intravenous fluids, intravenous antibiotics, steroids, nebulisers and non-invasive ventilation
	Intravenous fluids, intravenous antibiotics, nebulisers and steroids
	Intravenous fluids, oral antibiotics, nebulisers and steroids
	Oral fluids, intravenous antibiotics, nebulisers and non-invasive ventilation
	Oral fluids, oral antibiotics, nebulisers and steroids

Question 157 of 200

□ □

A 63-year-old man was admitted two hours ago with an infective exacerbation of COPD. He had become rapidly unwell following one day of a productive cough, developing worsening fever, shortness of breath and chest tightness. Arterial blood gas demonstrated that he was acidotic in type two respiratory failure despite treatment with back-to-back nebulisers, IV hydrocortisone and IV antibiotics. He was started on non-invasive ventilation (NIV) with IPAP of 10cmH₂O and EPAP of 4cmH₂O. This has been increased to IPAP of 16cmH₂O. During a review of this patient, the nurses ask what should be done about his nebulisers, prescribed 2 hourly, during NIV treatment.

How should he be treated with nebulisers whilst having NIV?

	Add nebulisers into NIV mask
	Take off mask to administer nebulisers
	Hold nebulisers whilst on NIV
	Give IV salbutamol instead of nebulised
	Stop NIV whilst on 2 hourly nebulisers

A 28-year-old male presents to the emergency department complaining of shortness of breath. For the last week he has felt generally unwell with a headache, malaise and lethargy, but felt breathless this afternoon hence his presentation. On systems review, he also admits to having some generalised abdominal pain throughout the day yesterday associated with diarrhoea. He is otherwise fit and well, takes no regular medications and does not smoke. He admits to drinking one or two beers every evening and occasionally more at the weekends. He is a primary school teacher and lives with his wife and two small children, none of whom have been unwell recently. On examination, he has a temperature of 38.9°C, a heart rate of 105 beats/minute and a blood pressure of 105/70 mmHg. His respiratory rate is 26 breaths/minute, his oxygen saturations 92% breathing room air and on auscultation to his chest there are a few crepitations bibasally. He has some routine blood tests performed.

Hb	109 g/L
MCV	105 fL
Platelets	390 * 10 ⁹ /L
WBC	16.5 * 10 ⁹ /L
CRP	240 mg/L
Bilirubin	50 µmol/L
ALT	40 u/L
ALP	135 u/L

What is the most likely diagnosis?

	Alcoholic liver disease
	Gilbert's syndrome
	Mycoplasma pneumonia
	Hypothyroidism

	Acute cholecystitis

□ Question 160 of 200

A 60-year-old caucasian female attends the respiratory clinic for review, She has been referred by her GP after presenting complaining of a chronic cough which has persisted for 6 months. The cough is productive, however she denies any haemoptysis. The patient's husband has commented that she appears to have lost weight during this time period, and she admits to unintentionally going down a dress size.

Before the onset of her cough, the patient reports that she had been reasonably fit and well, walking half an hour every day. She has never smoked and does not have any underlying respiratory pathology. She denies any history of fever or night sweats and has recently traveled to Italy for a summer holiday where she visited a famous bird sanctuary.

You review her chest radiograph which was performed prior to the clinic. There is an increased opacity in the right upper lung field. You perform a number of further investigations detailed below:

Hb	140g/l	Na ⁺	138 mmol/l
Platelets	400 * 10 ⁹ /l	K ⁺	5.0 mmol/l
WBC	11.0 * 10 ⁹ /l	Urea	3.0 mmol/l
Neuts	6.6 * 10 ⁹ /l	Creatinine	89 µmol/l
Lymphs	2.0 * 10 ⁹ /l	CRP	18 mg/l
Eosin	0.01 * 10 ⁹ /l	IFNγ-release assay	Negative
Sputum MC&S	Normal Flora	Sputum Acid Fast Bacilli (AFB)	Positive x 3

You also send the patient for a high resolution CT (HRCT) scan, which demonstrates a cavity in the right upper lobe with associated tree-in-bud appearances in the surrounding lung. There is no associated lymphadenopathy. What is the most likely causative organism for this presentation?

	Klebsiella species
	Mycobacterium tuberculosis
	Mycobacterium kansasii

	Allergic bronco-pulmonary aspergillosis (ABPA)
	Staphylococcal aureus

Dashboard

Overall score: **0%**

Question 161 of 200

□ □

A 48-year-old male presents to the respiratory clinic with his partner. They are concerned as he has lost 5 kgs in weight over the last three months. He also reports a productive cough which has been troubling him for a similar time period. He reports that he is currently producing approximately half a cup of phlegm each day. He denies fevers or night sweats and systems review is unremarkable.

You send the patient for a chest X-ray which is reported as showing multiple cavitating lesions. Sputum microscopy, sensitivities and culture (MC&S) are all negative and a HIV test is negative. You refer the patient for a bronchoscopy and bronco-alveolar lavage (BAL) to aid your diagnosis. Several weeks later you receive a call from the microbiology registrar on call to inform you that the patients sputum has cultured a non-tuberculous mycobacterium (*Mycobacterium intracellulare*).

You call the patient back into clinic and find that his symptoms have persisted since his last visit. What is the most appropriate management plan for this individual?

	Rifampicin, isoniazid, ethambutol, pyrazinamide
	Repeat sputum cultures
	Clarithromycin monotherapy
	Rifampicin, clarithromycin and ethambutol
	Rifampicin and isoniazid

He denies fevers or night sweats and systems review is unremarkable.

You send the patient for a chest X-ray which is reported as showing multiple cavitating lesions. Sputum microscopy, sensitivities and culture (MC&S) are all negative and a HIV test is negative. You refer the patient for a bronchoscopy and broncho-alveolar lavage (BAL) to aid your diagnosis. Several weeks later you receive a call from the microbiology registrar on call to inform you that the patient's sputum has cultured a non-tuberculous mycobacterium (*Mycobacterium intracellulare*).

You call the patient back into clinic and find that his symptoms have persisted since his last visit. What is the most appropriate management plan for this individual?

	Rifampicin, isoniazid, ethambutol, pyrazinamide
	Repeat sputum cultures
	Clarithromycin monotherapy
	Rifampicin, clarithromycin and ethambutol
	Rifampicin and isoniazid

Question 162 of 200

□ □

You review a 67-year-old patient in the respiratory clinic with a known diagnosis of chronic obstructive pulmonary disease. He has a 30 pack year smoking history. He remains breathless despite taking inhaled Atrovent (ipratropium) as required started by his GP. On recent spirometry his FEV1 is 54% predicted. On examination today there is bilateral wheeze but no signs of right ventricular failure. Oxygen saturations on air are 94%. What would be the most appropriate next step in inhaled treatment?

	Combivent (salbutamol + ipratropium), discontinue Atrovent
	Fostair (beclomethasone + formeterol), continue Atrovent
	QVAR (beclomethasone), continue Atrovent
	Salbutamol, continue Atrovent
	Spiriva (tiotropium), discontinue Atrovent

Question 163 of 200

□ □

A 43-year-old Afro-Caribbean male presents with sudden onset palpitations and feeling generally unwell for 2 hours. An admission ECG in the emergency department demonstrates ventricular tachycardia. His heart rate is 80 beats/ minute with a blood pressure of 140/75mmHg. The patient is chemically cardioverted back to sinus rhythm with a single intravenous bolus of amiodarone. The patient was commenced on haemodialysis 9 months ago after developing end-stage renal failure over a course of 16 months with no conclusive underlying cause found for the deteriorating renal function. He also complains of a new dry cough over the past 18 months, weight loss of at least one and a half stone and general malaise, which he attributes to his deteriorating kidneys.

On examination, the patient has normal heart sounds with no additional murmurs. Auscultation of his chest demonstrates biapical fine inspiratory crackles with no wheeze. Abdominal examination reveals a mild 2cm hepatomegaly with no splenomegaly. An arteriovenous fistula is noted in the left brachiocephalic region. No skin rashes are noted. An admission chest X-ray demonstrates no clear consolidation, reticular opacities in both apices and prominent bilateral hilar, with no cardiomegaly or tramlining.

Blood tests are as follows:

Hb	134 g/l
Platelets	$292 \times 10^9/l$
WBC	$12.5 \times 10^9/l$

Na ⁺	131 mmol/l
K ⁺	5.9 mmol/l
Urea	22.6 mmol/l
Creatinine	540 μ mol/l

Bilirubin	17 μ mol/l
ALP	55 u/l
ALT	70 u/l

CRP	12 mg/l
ACE (angiotensin converting enzyme)	negative

Pulmonary function tests: FVC 60% predicted FEV1 92% predicted

A bronchoalveolar lavage is performed, demonstrating lymphocytosis of 25%, CD4:CD8 ratio of 5:1, a transbronchial biopsy demonstrates non-caseating granulomas.

What is the underlying diagnosis?

	Human immunodeficiency virus (HIV)
	Miliary tuberculosis
	Amyloidosis
	Sarcoidosis
	Lymphoma

Question 164 of 200

□ □

A 79-year-old woman is brought in by ambulance to the emergency department. She has been feeling progressively unwell with a productive cough. She has coughed up rusty coloured phlegm for the last seven days and has also seen streaks of blood in the last two days. She has been feeling nauseous and been off her food too. She has a past medical history of hypertension, glaucoma and diverticular disease.

On examination, she has unilateral crepitations in her chest, appears unwell and feels hot and clammy to touch. Her observations show blood pressure of 105/63mmHg, oxygen saturations of 92% on 3L of oxygen via nasal cannula, a temperature of 38.2°C, respiratory rate of 27/min, and a heart rate of 91/min. Her blood tests are pending. Her abbreviated mental test score (AMTS) is 8/10.

Apart from her age, what is a predictor for severity of chest infection for her?

	Temperature
	Blood pressure
	Respiratory rate
	Heart rate
	AMTS

□ Question 167 of 200

□ □

A 59-year-old man is investigated for increasing shortness-of-breath. This has been getting progressively worse for the past 6 months and is associated with a dry cough. He has received two courses of antibiotics from his GP which only temporarily improved his symptoms. He was diagnosed with asthma as a child but has not had to use an inhaler since he was around 10-years-old. He stopped smoking 20 years ago.

On examination he is noted to have scattered crackles bilaterally, predominantly in the bases. Oxygen saturations are 96% on room air. Pulse, blood pressure and temperature are normal.

Spirometry is arranged:

FEV1	2.2 L (predicted 3.8 L)
FVC	2.7 L (predicted 4.5 L)
FEV1/FVC	81% (normal > 75%)

A chest x-ray is arranged:

© Image used on license from Radiopaedia

Which one of the following interventions is most likely to be beneficial?

	Bosentan
	Rotation of prophylactic antibiotic + postural drainage
	Bronchodilator therapy
	Prednisolone
	Pirfenidone

Question 170 of 200

□ □

A 91-year-old man is admitted into hospital with a severe exacerbation of his COPD. He is breathless on rest and although alert and orientated, is starting to become drowsy. His observation reveal a temperature of 37.9°C, a heart rate of 82 beats per minute, blood pressure of 116/74 mmHg, respiratory rate of 28 breaths per minute and oxygen saturations of 84% on a 28% Venturi mask.

An arterial blood gas is performed and reveals a PaO₂ of 9.0 kPa, PCO₂ of 11.4kPa, HCO₃ of 31 mmol/l and a pH of 7.29.

A decision is made to commence the man on non-invasive ventilation - which of the following is the most appropriate management for this patient?

	Inspiratory positive airways pressure (IPAP) of 10cm water and expiratory positive airways pressure (EPAP) of 4cm water at 60% flow rate of oxygen
	Inspiratory positive airways pressure (IPAP) of 10cm water and expiratory positive airways pressure (EPAP) of 4cm water at 20% flow rate of oxygen
	Inspiratory positive airways pressure (IPAP) of 10cm water and expiratory positive airways pressure (EPAP) of 4cm water at 40% flow rate of oxygen
	Inspiratory positive airways pressure (IPAP) of 10cm water and expiratory positive airways pressure (EPAP) of 6cm water at 40% flow rate of oxygen

Question 171 of 200

□ □

A 40-year-old lady presents with dyspnoea. She describes a gradual onset of shortness of breath on exercise over several months. She has a past medical history of wheeze as an infant. She has recently commenced a intranasal steroid spray for rhinitis. She is a non-smoker.

On examination she has oxygen saturations of 91% on air. She has blood stained crusting around her anterior nares. On auscultation her chest has bilateral reduced air entry and coarse crepitations on both lung bases. Her temperature is 37.8 degrees centigrade.

Hb	13.2 g/dL
WCC	$10.3 \times 10^9/l$
Neutrophil	$7.8 \times 10^9/l$
Eosinophil	$0.07 \times 10^9/l$

Sodium	135 mmol/l
Potassium	4.5 mmol/l
Creatinine	113 μ mol/l
Urea	5.4 mmol/l

CRP	230 mg/L
Chest X - ray	Bilateral basal consolidation
Urine microscopy	Culture negative RBC +++ WCC +
c-ANCA	Positive
p-ANCA	Positive
Anti-GBM	Negative

What is the most likely diagnosis?

	Pneumonia
	Churg-Strauss Syndrome
	Microscopic polyangiitis
	Granulomatosis with polyangiitis
	Goodpastures disease

Dashboard

Question 172 of 200

A 42 year old lady presents to the Emergency Department with a 3 week history of dry cough, fever and lethargy. She has no past medical history and takes no regular medications. There is no history of recent foreign travel. Clinical examination reveals inspiratory crepitations affecting the left upper zone and R lower zone. Saturations are 91% on room air. Chest x-ray shows bilateral peripheral pulmonary infiltrates.

Bloods show:

Hb	110 g/L
MCV	78 fL
WCC	$13 \times 10^9/L$
Neutrophils	$8 \times 10^9/L$
Lymphocytes	$1 \times 10^9/L$
Eosinophils	$3.1 \times 10^9/L$
Platelets	$560 \times 10^9/L$
CRP	115mg/l

What is the most appropriate treatment given the likely diagnosis?

	Oral prednisolone
	High dose co-trimoxazole
	Plasma exchange
	Rifampicin, isoniazid, ethambutol and pyrazinamide
	Amoxicillin and clarithromycin

Dashboard

□ Question 173 of 200

□ □

A 40-year-old woman with a history of poorly controlled asthma is reviewed in the respiratory clinic. Her GP has tried a number of courses of antibiotics recently but her symptoms of wheeze and a productive cough have not resolved. Her inhalers have also been changed with the addition of long-acting beta agonist in addition to her salbutamol and corticosteroid inhalers, but again this has not improved her symptoms.

Routine bloods requested by the GP show the following:

Hb	12.3 g/dl	Na ⁺	141 mmol/l
Platelets	362 * 10 ⁹ /l	K ⁺	4.2 mmol/l
WBC	10.6 * 10 ⁹ /l	Urea	5.2 mmol/l
Neuts	6.9 * 10 ⁹ /l	Creatinine	69 µmol/l
Lymphs	2.3 * 10 ⁹ /l	CRP	35 mg/l
Eosin	1.4 * 10 ⁹ /l		

A chest x-ray shows the following:

Question 174 of 200

□ □

A 77-year-old active smoker with a 40 pack year history presents with his second non-infective exacerbation of COPD in 3 months. He was diagnosed with COPD two years ago and had been relatively well controlled using salbutamol as required prior to these two admissions. Two days after his admission, he reports that he is close to his baseline and would like to go home. His repeat pulmonary function tests reveal a forced expiratory volume in 1 second of 46%. Which would be most useful in optimising his COPD control?

	No change to inhaler therapy, follow up in 3 months
	Add beclometasone inhaler alone
	Add salmeterol and fluticasone combination inhaler
	Add salmeterol inhaler alone
	Long term oxygen therapy

Question 175 of 200

□ □

You review a 57-year-old man. He was diagnosed with having asthma around 12 months ago after presenting with a persistent wheeze that was worse on exertion and at night time. A trial of salbutamol and initially improved his symptoms but he developed an infective exacerbation over winter and had Clenil 200mcg bd added to his medication around 3 months ago. Unfortunately his symptoms have not improved and he is more short-of-breath on exertion and has a persistent cough. You check his inhaler technique which is good. He gave up smoking 6 months ago, drinks alcohol in moderation and has a body mass index of 25 kg/m². What is the most important next step in management?

	Add a leukotriene receptor antagonist
	Add salmeterol
	Arrange a chest x-ray
	Increase the dose of Clenil
	Arrange spirometry

Dashboard

□ Question 176 of 200

A 58-year-old smoker was referred to the respiratory outpatient clinic by his GP with a history of progressively worsening shortness of breath. His symptoms started several months ago with shortness of breath on extreme exertion but he gradually developed shortness of breath with minimal activity. He also complained of increasing tiredness and a non-productive cough had lost approximately 3 pounds in 6 months. He denied the presence of sputum production, haemoptysis or chest pain, and also denied the presence of both orthopnoea and paroxysmal nocturnal dyspnoea. He had a past medical history comprising ankylosing spondylosis diagnosed 30 years ago as well as hypertension and hypercholesterolaemia. His drug history comprised naproxen 500mg BD, lansoprazole 30mg OD, felodipine M/R 2.5mg OD and atorvastatin 20mg OD. He stated that he had been trialled with a course of methotrexate a few years ago for his ankylosing spondylosis and was subsequently stopped.

Examination revealed the presence of a well male with a blood pressure of 146/86 mmHg, heart rate 74 bpm and respiratory rate of 18/min. His oxygen saturations were 93% on air. There was no BCG scar seen on examination of his arm. Examination of his respiratory system revealed the presence of bilateral fine upper zone crackles but nil else and no respiratory distress. Examination of his cardiovascular system revealed no abnormalities including a normal JVP and the absence of pedal oedema, and examination of his gastrointestinal system was likewise unremarkable.

Initial investigations revealed the following:

Hb	166 g/l
Platelets	341 * 10 ⁹ /l
WBC	6.3 * 10 ⁹ /l
ESR	34 mm/hr
CRP	26 mg/l

Chest x-ray: Bilateral apical fibrosis

Pulmonary function testing

- FEV1 2.4 l (predicted value 2.3)
- FVC 2.6 l (predicted value 4.8)
- FEV1/FVC ratio 92%
- TLCO transfer factor 86% of predicted value

What is the most likely diagnosis?

	Pulmonary hypertension
	Pulmonary tuberculosis
	Pulmonary fibrosis secondary to methotrexate
	Extrinsic allergic alveolitis (EAA)
	Pulmonary fibrosis secondary to ankylosing spondylosis

Dashboard

Question 181 of 200

□ □

A 63-year-old man is commenced on anti-tuberculosis therapy, after presenting hospital with a history of several months of weight loss, shortness of breath and a productive cough which was sometimes accompanied by haemoptysis. A chest x-ray had revealed apical consolidation and sputum was positive for acid-fast bacilli, thus a diagnosis of tuberculosis was then made. His only past medical history includes a diagnosis of asthma for which he takes PRN salbutamol and seretide (25 micrograms of salmeterol and 125 micrograms of fluticasone propionate) inhaler twice daily.

A week after being diagnosed, he is admitted to the acute medical unit with shortness of breath and bilateral expiratory wheeze. His observations reveal a temperature of 37.1°C, respiratory rate of 27 breaths per minute and oxygen saturations of 94% on room air. Oxygen is commenced via a face mask. A chest x-ray reveals the same hilar consolidation as before, with no new features.

What is the most appropriate next step in her treatment?

	Continue the tuberculosis medication at current dose and increase the steroid dose
	Continue the tuberculosis medication at current dose and decrease the steroid dose
	Reduce the tuberculosis medication and increase the steroid dose
	Stop the tuberculosis medication and increase the steroid dose
	Continue the tuberculosis medication at current dose and keep the steroid dose the same

Question 181 of 200

□ □

A 63-year-old man is commenced on anti-tuberculosis therapy, after presenting hospital with a history of several months of weight loss, shortness of breath and a productive cough which was sometimes accompanied by haemoptysis. A chest x-ray had revealed apical consolidation and sputum was positive for acid-fast bacilli, thus a diagnosis of tuberculosis was then made. His only past medical history includes a diagnosis of asthma for which he takes PRN salbutamol and seretide (25 micrograms of salmeterol and 125 micrograms of fluticasone propionate) inhaler twice daily.

A week after being diagnosed, he is admitted to the acute medical unit with shortness of breath and bilateral expiratory wheeze. His observations reveal a temperature of 37.1°C, respiratory rate of 27 breaths per minute and oxygen saturations of 94% on room air. Oxygen is commenced via a face mask. A chest x-ray reveals the same hilar consolidation as before, with no new features.

What is the most appropriate next step in her treatment?

	Continue the tuberculosis medication at current dose and increase the steroid dose
	Continue the tuberculosis medication at current dose and decrease the steroid dose
	Reduce the tuberculosis medication and increase the steroid dose
	Stop the tuberculosis medication and increase the steroid dose
	Continue the tuberculosis medication at current dose and keep the steroid dose the same

Question 182 of 200

□ □

A 29-year-old man presents to his GP with shortness of breath. This has been occurring for the past 6 months and is sometimes accompanied by wheezing, particularly later on during the day. He does not have any past medical history and occasionally takes over-the-counter antihistamines for hay-fever. His only recent travel history is a holiday to Greece, where he found he was less short of breath and he was less wheezy. His only family history of note is his mother who died of a heart attack aged 65. He works as a car mechanic and smokes 5 roll-up cigarettes per day and drinks on average 5-6 units of alcohol per week.

Examination of the chest is normal with good air entry bilaterally and no added sounds. Heart sounds I and II are present with no obvious murmurs.

What is the most useful investigation in determining this man's diagnosis?

	Chest x-ray
	Peak expiratory flow rate measurements at both home and at work
	Pulmonary function testing
	Serum IgE measurement
	Skin prick testing

Question 183 of 200

□ □

A 27-year-old woman with brittle asthma presents to the Emergency department. She is managed with high dose salmeterol/fluticasone and montelukast but reports steadily worsening symptoms since starting with a cold some 48hrs earlier. She has been admitted to the intensive care unit on 3 previous occasions. On examination her blood pressure is 122/82 mmHg pulse rate is 88 beats per minute. On auscultation of her chest you hear quiet breath sounds with polyphonic wheeze, her respiratory rate is 30/min. She is given back to back salbutamol nebulisers, ipratropium nebulisers, and IV hydrocortisone. These interventions only lead to minimal improvement in her PEFR from 110 to 140, (330 predicted). Oxygen saturation is 92% measured by pulse oximeter, on 60% oxygen delivered via mask. You call the anaesthetist for possible intubation.

Which of the following is the most appropriate next step?

	IV aminophylline
	IV chlorpheniramine
	IV magnesium
	IV salbutamol
	IV omalizumab

Question 184 of 200

A 71-year-old woman is referred by her GP to the rapid access chest clinic with progressive shortness of breath and reduced exercise tolerance over 3 months and a chronic productive cough. When asked about her past medical history she states that she has had some pain for the past month or so in her left shoulder, which has been present at a constant level. She has been taking paracetamol and codeine for the pain which helps slightly. Otherwise, the patient has moderate COPD, for which she taken ipratropium bromide and salmeterol and mechanical back pain. She has a 15 year pack-history and drinks 1-2 units of alcohol per day.

Examination reveals some wasting of the hypothenar eminence of the left hand, although the chest sounds clear bilaterally with no added sounds. Heart sounds 1 and 2 are present with no murmurs.

What would be the most useful investigation following a chest x-ray?

<input type="checkbox"/>	Electromyogram studies
<input type="checkbox"/>	Computed tomography of the thorax
<input type="checkbox"/>	Bronchoscopy
<input type="checkbox"/>	Myeloma screen
<input type="checkbox"/>	Sputum microscopy, culture and sensitivity

Question 185 of 200

A 72-year-old gentleman presents with a five month history of dry cough and worsening shortness of breath on exertion. He undergoes extensive investigations and is diagnosed with idiopathic pulmonary fibrosis.

Bloods performed as part of the diagnostic work up show:

Hb	141 g/l
Platelets	$255 \times 10^9/l$
WBC	$5.2 \times 10^9/l$
ESR	32 mm/h

Na ⁺	139 mmol/l
K ⁺	3.6 mmol/l
Urea	4.7 mmol/l
Creatinine	92 μ mol/l
CRP	15 mg/L

His lung function tests show a forced vital capacity (FVC) of 65% of predicted.

On examination the patient has obvious finger clubbing and fine end-inspiratory crepitations on auscultation of the chest.

Of note in his past medical history he smoked for ten years between the ages of 20 and 30.

He is understandably very distressed by the diagnosis and asks about potential therapies. He is enrolled on a pulmonary rehabilitation programme but is keen to try a pharmacological therapy. Which drug should be considered in this patient?

	Azathioprine
--	--------------

	Prednisolone
	Bosentan
	Pirfenidone
	Sildenafil

Question 186 of 200

A 27-year-old lady was admitted to the Emergency Department due to acute shortness of breath. She had been completely normal that morning. Her sister mentioned that this was not the first time she had suffered such an attack and she improved every time after staying in hospital for a couple of hours and taking some nebulisers. The patient is not known to have any medical condition. Her father is on long term prednisone tablets and nebulisers for chronic obstructive pulmonary disease.

On examination: blood pressure 123/86 mmHg, pulse rate 110/min, respiratory rate 35/min. Oxygen saturation 98%. The chest was clear with good air entry.

Blood investigations showed:

Hb	128 g/l
Platelets	320 * 10 ⁹ /l
WBC	8 * 10 ⁹ /l
Na ⁺	137 mmol/l
K ⁺	4.2 mmol/l
Urea	6 mmol/l
Creatinine	100 µmol/l

A 3-month-old pulmonary function test was normal.

What is the next step in management?

<input type="checkbox"/>	Discharge home
<input type="checkbox"/>	Refer to repeat pulmonary function tests

□ Question 187 of 200

A 28-year-old presents to Accident and Emergency with symptoms of increasing shortness of breath, wheeze and a cough.

This is her first hospital attendance with asthma which is usually well controlled. She has a past medical history of perennial rhinitis.

She has no known drug allergies and takes beclomethasone (200 micrograms inhaled twice a day) and salbutamol which she rarely uses. She has never smoked

On examination her respiratory rate is 24, her pulse is 98 bpm and has widespread wheeze on auscultation of her chest. Her oxygen saturations on air are 93%. She is quiet, anxious and seems disoriented.

Blood tests reveal a raised white cell count of $11 \times 10^9/L$, her chest x-ray is normal.

She is started on nebulised salbutamol and ipratropium bromide and given an oral dose of prednisolone.

An arterial blood gas is taken 5 minutes after being started on 40% oxygen:

pH	7.36
PaO ₂	16.0 kPa
PaCO ₂	5.98 kPa
Bicarbonate	19 mmol/l

What would be the most appropriate next step?

	Secure a cannula and give 200mg of hydrocortisone IV
	Start empirical antibiotics
	Magnesium infusion

	Arrange a review by an anaesthetists/intensivist
	Repeat an arterial blood gas after 10 minutes

Question 188 of 200

A 22-year-old second generation British Pakistani is seen by the Tuberculosis (TB) Specialist Nurse as part of the contact tracing service. Her mother has recently been diagnosed with active TB after presenting to the respiratory clinic with a 3-month history of night sweats, weight loss, and haemoptysis.

The patient is clinically well and denies any focal symptomatology. Her past medical history is unremarkable and she is a non-smoker. She studies full-time at university but continues to live at home with her extended family. She was fully immunised as a child.

On examination, she is afebrile. Her respiratory rate is 16/min and her oxygen saturations are 97% breathing room air. There is no cervical lymphadenopathy, her chest is clear and her abdomen is soft and non-tender.

A Mantoux test is performed and read 72 hours later, at which time a 7mm area of induration is noted lying within a 16mm area of erythema. An interferon-gamma release assay (IGRA) is requested. What does a positive IGRA indicate?

	Latent TB or prior immunisation
	Latent TB
	Prior immunisation
	Active or latent TB
	Active TB or prior immunisation

Mrs Stevens is a 60-year-old lady with pulmonary fibrosis secondary to dermatomyositis. She returns to your clinic seven weeks after being commenced on high dose steroids due to disease progression. During the review Mrs Stevens describes increasing shortness of breath, which is worse when she exerts herself. She has not noticed any fever and has not lost any weight. She has a chronic cough productive of white sputum. This remains stable.

On examination she looks comfortable at rest and auscultation of her chest is surprisingly clear. At rest her oxygen Sats are 97%. You ask her to walk to the end of the corridor and back. You notice that on returning her Sats have fallen to 82%. You request an urgent chest radiograph, which is reported as showing bilateral patchy infiltrates.

What is the most appropriate management option?

	Fluconazole
	Ambisome
	Co-trimoxazole
	Ribavirin
	Stop steroids

Question 190 of 200

□ □

A 28-year-old man is referred by A&E to the acute medical team. He is a Swedish student studying for his PhD at the local university. He complains of a 6-week history of a non-productive cough associated with fevers. He denies haemoptysis or weight but admits that his exercise tolerance has reduced over the same period. He also reports pains in his knees, ankles and wrists and some painful red swellings on his legs. He admits to having had these before several years ago but they went away without any medical treatment and left no scars. He denies any bowel symptoms. On examination, he is afebrile and cardiovascularly stable. His respiratory rate is 18 at rest and his saturations are 96% on air. He has no palpable lymphadenopathy and his respiratory examination is normal, as is cardiovascular and abdominal examinations. His shins have bilateral tender red nodules on them.

His bloods results done by A&E are:

Hb	145 g/l
Platelets	$365 \times 10^9/l$
WBC	$9.1 \times 10^9/l$
Neuts	$5.1 \times 10^9/l$

Na ⁺	140 mmol/l
K ⁺	4.2 mmol/l
Urea	5.4 mmol/l
Creatinine	82 μ mol/l

Bilirubin	4 μ mol/l
ALP	59 u/l
ALT	23 u/l
Albumin	43 g/l
CRP	5 mg/l

Adjusted calcium	2.65 mmol/l
------------------	-------------

His chest x-ray shows bilateral hilar lymphadenopathy with some small bilateral pulmonary infiltrates.

He goes on to have a CT chest which confirms the above findings. A bronchoscopy is performed which is normal and transbronchial biopsies of the hilar lymph nodes show non-caseating granulomas.

What is the most appropriate treatment for this gentleman?

	Prednisolone
	NSAIDs
	R-CHOP
	Methotrexate
	Nothing

Neuts	$5.1 \times 10^9/l$

Na ⁺	140 mmol/l
K ⁺	4.2 mmol/l
Urea	5.4 mmol/l
Creatinine	82 μ mol/l

Bilirubin	4 μ mol/l
ALP	59 u/l
ALT	23 u/l
Albumin	43 g/l
CRP	5 mg/l

Adjusted calcium	2.65 mmol/l
------------------	-------------

His chest x-ray shows bilateral hilar lymphadenopathy with some small bilateral pulmonary infiltrates.

He goes on to have a CT chest which confirms the above findings. A bronchoscopy is performed which is normal and transbronchial biopsies of the hilar lymph nodes show non-caseating granulomas.

What is the most appropriate treatment for this gentleman?

	Prednisolone
	NSAIDs
	R-CHOP
	Methotrexate
	Nothing

Question 191 of 200

A 65 year-old woman presents with a 7 month history of shortness of breath. She also has a cough, which is predominantly non-productive. Despite three course of antibiotics from her general practitioner, her symptoms have worsened. She now struggles to climb the stairs without getting breathless and has had to take early retirement from work. She is still able to sleep lying flat and does not wake up at night feeling breathless.

She has systemic sclerosis, which was diagnosed in her twenties. She is under the rheumatology team for this, and has been taking ibuprofen and nifedipine for the last 3 years with good symptomatic control. She also has allergic rhinitis. She is a current smoker of 10 cigarettes a day and started smoking when she was 20. She was treated for latent tuberculosis as a child, but is unable to recall any treatment details.

Heart rate- 90 beats per minute

Blood pressure- 130/80 mmHg

Respiratory rate- 20 breathes per minute

Oxygen saturations- 93% on room air

Temperature- 37.4°C

Hb	115 g/l	Na ⁺	140 mmol/l
Platelets	350 * 10 ⁹ /l	K ⁺	3.7 mmol/l
WBC	11.5 * 10 ⁹ /l	Urea	7.5 mmol/l
Neuts	7.5 * 10 ⁹ /l	Creatinine	100 µmol/l
CRP	10 mg/l		

What is the most likely diagnosis?

	Lung carcinoma
	Chronic obstructive pulmonary disease
	Primary pulmonary hypertension

	Pulmonary fibrosis
	Acute interstitial pneumonitis

Question 193 of 200

□ □

A 55-year-old woman is reviewed in respiratory clinic. She was referred GP following investigations for chronic progressive exertional breathlessness and found to have a restrictive pattern on spirometry with a reduced forced vital capacity. She has undergone a high-resolution CT scan of her chest which demonstrates ground-glass changes. Following clinical review, she is told that the most likely diagnosis is idiopathic pulmonary fibrosis. She is very keen to exclude any other cause; what is the most appropriate way of confirming the diagnosis?

	Open lung biopsy
	Broncho-alveolar lavage
	Video-assisted thoracoscopy (VATS)
	Trans-bronchial lung biopsy
	Measurement of serum ACE

□ Question 195 of 200

A 71-year-old woman is referred by her out-of-hours GP service to the emergency department following her presentation with worsening shortness of breath and cough. The shortness of breath has been increasing in severity over the last 3 weeks and is associated by an occasional non-productive cough.

She has an extensive cardiac past medical history including two myocardial infarctions which were treated with percutaneous coronary intervention, an aortic heart valve replacement and mild mitral regurgitation. Other history includes hypertension which is treated with amlodipine and ramipril, hypercholesterolaemia which is treated with atorvastatin and mild COPD for which he takes salbutamol and ipratropium bromide. She previously worked as a librarian, has smoked 10 cigarettes for the past 20 years and drinks on average 5 units of alcohol per week.

Examination reveals dull percussion and reduced breath sounds over the left mid and lower bases of the lung. Urgent chest x-ray reveals a left-sided pleural effusion. Pleural aspirate is taken and shows:

Protein content	45 g/L
Glucose	2.4mmol/L
pH	7.32

What is the most likely diagnosis?

	Congestive cardiac failure
	Bronchial carcinoma
	Systemic lupus erythematosus
	Mesothelioma
	Boerhaave's syndrome

Question 197 of 200

A 25-year-old lady is admitted via the Emergency Department with shortness of breath, dry cough and wheeze. She has a past history of asthma and hayfever.

Her cough developed whilst on holiday in Cornwall a week ago. Since returning, she has visited her GP and been given a course of amoxicillin. She subsequently developed diarrhoea and headaches. None of her family has been unwell.

On examination she has saturations of 94% on air and a respiratory rate of 24/min. Her heart rate is 105/min and her blood pressure is 118/72 mmHg. Her temperature is 37.8 °C. She is able to complete sentences and her peak flow is 53% of her predicted. On auscultation she has right basal a crepitations and widespread wheeze. Her abdomen is soft and non-tender with normal bowel sounds. She has multiple soft, mildly enlarged cervical lymph nodes but no palpable nodes elsewhere.

Her chest x-ray shows a right basal consolidation.

Her blood tests are as follows:

Hb	120 g/l	Na ⁺	138 mmol/l	Bilirubin	4 µmol/l
Platelets	450 * 10 ⁹ /l	K ⁺	3.5 mmol/l	ALP	72 u/l
WBC	16 * 10 ⁹ /l	Urea	8 mmol/l	ALT	13 u/l
Neuts	14 * 10 ⁹ /l	Creatinine	82 µmol/l	CRP	35 mg/l

She is treated with salbutamol and ipratropium nebulisers, steroids and IV antibiotics.

Which test is most likely to reveal the causative organism?

	Blood cultures
	Legionella urinary antigen
	Mycoplasma serology

	Respiratory virus swab
	Sputum culture

Question 198 of 200

□ □

A 74-year-old ex-miner is reviewed in the Respiratory Clinic with a 4-month history of episodic dyspnoea and dry cough. The attacks last for several days at a time and are accompanied by fever, malaise, and chest tightness. He recovered from the most recent episode 2 weeks ago.

His past medical history is unremarkable and he states that he is generally well between episodes. He does report some long-standing shortness of breath on exertion, but this has been stable for the past 6 years and he estimates his exercise tolerance at 200 yards.

He worked as a miner until the early 1980s and then retrained as a plumber. He continued to work until his retirement in the early 2000s. He now enjoys housing pigeons in his back garden. He does not smoke.

On examination, his respiratory rate is 14/min and his oxygen saturations are 95% breathing room air. His fingers are clubbed and there are bibasal crackles on auscultation of the chest. His heart sounds are dual with nil added.

A high-resolution CT (HRCT) scan of the thorax is reported as showing subpleural bibasal reticular opacities with some evidence of honeycombing but no appreciable ground-glass opacification.

What is the most likely cause of his symptoms?

	Asbestosis
	Hypersensitivity pneumonitis
	Silicosis
	Coal worker's pneumoconiosis
	Idiopathic pulmonary fibrosis

Overall score: **0%**

□ □

A 72-year-old man is admitted to hospital for an elective knee replacement. The surgery is completed successfully and induction, maintenance and emergence of anaesthesia proceeds without any problem. Several hours after the operation however, the patient's saturations start to drop, reaching a level of 91% when the patient is started on oxygen via face mask. He also starts coughing up small mucous plugs.

His background history includes mild COPD that is treated with tiotropium and hypertension which is treated with ramipril and amlodipine. There is no relevant family history and he has smoked 15 cigarettes a day for 30 years.

What is the most likely diagnosis?

	Basal atelectasis
	<i>Pneumococcus pneumoniae</i>
	<i>Streptococcus pneumoniae</i>
	Pulmonary embolism
	Pneumothorax

Question 3 of 94

A 51-year-old man presents to the emergency department with a 2-week history of lumbar back pain. He has a background of asthma, hypertension and benign prostatic hypertrophy (BPH). He has no history of trauma. Apart from a recent exacerbation of asthma, he is otherwise well.

On examination, you find a man of large body habitus. He is able to mobilise with some discomfort. He is afebrile, with a heart rate of 75 beats per minute and blood pressure 120/82mmHg. He has some spinal tenderness at L4, and discomfort on extension of the spine. On neurological examination he has no muscle wasting or fasciculations. He has full power in all limbs and normal tone. Reflexes are symmetrical and plantars downgoing. Sensation is intact and he has normal rectal tone, with no saddle anaesthesia.

Blood tests show:

Hb	14.1 g/dl
Platelets	245 * 10 ⁹ /l
WBC	8.0 * 10 ⁹ /l

Na ⁺	137 mmol/l
K ⁺	4.0 mmol/l
Urea	5.1 mmol/l
Creatinine	82 µmol/l

Bilirubin	14 µmol/l
ALP	42 u/l
ALT	17 u/l
CRP	3 mg/L
PSA	3.1ng/mL

What is the most likely diagnosis?

	Paget's disease
	Infective discitis
	Spinal metastases
	Vertebral compression fracture
	Lumbar radiculopathy

□ Question 5 of 94

A 38-year-old Armenian visitor presents with 3 day history of pyrexia, shortness of breath, chest pain and abdominal pain, associated with temperature of 38.5 degrees. She has no other known past medical history and reports at least 2 other episodes of similar pain, both times spontaneously resolving without treatment or diagnosis. On examination, she has a pleural rub and a swollen, tender left 3rd metcarpal-phalangeal joint. Her mother has recently been admitted for similar symptoms last month. Her blood tests are as follow:

Hb	14.5 g/dl
Platelets	$560 \times 10^9/l$
WBC	$17.8 \times 10^9/l$

Na ⁺	143 mmol/l
K ⁺	4.6 mmol/l
Urea	5.2 mmol/l
Creatinine	78 μ mol/l
CRP	78 mg/l

A chest radiograph demonstrates mild bilateral pleural effusions with no significant focus of consolidation, her Mantoux test is negative. Urine dip is negative, urine MC+S grows no organisms, urinary porphobilinogen is negative. A rheumatology review was requested regarding the synovitis and colchicine prescribed. She responds well with resolution of all symptoms within 24 hours. An infectious diseases opinion and induced sputum is awaited. What is the most likely diagnosis?

	Tuberculosis
	Acute intermittent porphyria (AIP)
	Coxsackie B virus infection

	Familial mediterranean fever
	Systemic lupus erythematosus (SLE)

Question 6 of 94

□ □

A 68 year old female diagnosed with rheumatoid arthritis four years ago presents gradually increasing tenderness in the small joints of both hands over the past 5 months. She continues to work as a legal secretary, involving significant amounts of time at a computer. She is currently on maximum doses of methotrexate and sulphasalazine on diagnosis and maintained on the same doses since. Her DAS score today is 5.8, it was 4.7 when you saw her in clinic last 1 month ago. What is the next management step?

	Continue methotrexate and sulphasalazine. Short-course oral prednisolone
	Stop current DMARDs. Start etanercept
	Stop current DMARDs. Start infliximab
	Admit for pulsed intravenous methylprednisolone
	Prescribe regular long-term celecoxib in addition to methotrexate and sulphasalazine

Dashboard

□ Question 8 of 94

□ □

A 74-year-old female was admitted to the medical ward initially for the treatment of a CURB = 4 community-acquired pneumonia. She is now awaiting discharge but since her illness, she has not returned to her pre-morbid state. Her past medical history includes two previous myocardial infarctions, hypertension, type 2 diabetes mellitus, duodenal ulcer and obesity. In addition, the physiotherapists report significant right knee pain to be contributing to poor mobility. On questioning, the patient reports that the pain is chronic and has been progressively worsening for about 3 years.

Her GP had sent her for two X-rays previously that demonstrated cartilage loss and osteophyte formation, with a reduction in joint space. On examination, you note significant crepitus in the right knee, with reduced range of movements in flexion and extension. You also note bony outgrowths in the proximal interphalangeal joints of her second and third digits of her right hand. She had successfully lost 9kg in weight and had previously taken 1g paracetamol four times a day regularly but neither measure seemed to help her pain.

What is the most appropriate next step?

	Increase 500mg paracetamol as required
	Oral ibuprofen
	Topical diclofenac
	Oramorph as required
	Glucosamine

Dashboard

Overall score: 0%

□ Question 11 of 94

A 45 year old woman was referred to Rheumatology clinic after experiencing widespread aches and pains felt throughout her body. The pains were felt particularly in her arms and legs in addition to significant pain throughout the patients spinal column. The patient could not recall a precise onset of her symptoms but she felt they had been present for at least 12 months, possibly longer. In addition, the patient reported on-going feelings of tiredness and lethargy. Despite going to bed around 10 pm each evening, the patient reported waking in the morning still feeling exhausted. She denied any history of hot or tender joints, skin rashes, hair loss, swallowing difficulties or dry eyes. The patients appetite was described as normal for her with no significant change in weight.

There was no previous past medical history and the patient took no regular medications except for a non-prescription multi-vitamin. Family history was remarkable for hypothyroidism affecting her mother and elder sister. The patient worked as an accountant and lived with her two teenage children. She had separated from her ex-husband 18 months previously.

Examination did not demonstrate any evidence of active synovitis of the hands or feet with no other inflamed or deformed joints. Palpation of the muscles of the upper arms and legs as well as the paraspinal muscles was exquisitely tender. Neurological examination of the arms and legs was unremarkable. Cardiovascular and respiratory examination was unremarkable with no skin rashes.

During clinic interaction the patient appeared tired and stressed but had good rapport and maintained good eye contact. She denied any significant low mood but was anxious that her symptoms represented a serious underlying illness.

Investigations requested following clinic are listed below.

Haemoglobin	12.9 g / dL
White cell count	$7.2 \times 10^9/l$
Platelets	$332 \times 10^9/l$
Mean cell volume	87 fL
Sodium	140 mmol / L
Potassium	3.6 mmol / L
Urea	3.5 mmol / L

Creatinine	68 micromol / L
Erythrocyte sedimentation rate	11 mm / h
Rheumatoid factor	Negative
Anti-nuclear antigen	Weak positive
B12	324 pmol / L (reference 74-516)
Folate	30 nmol / L (reference 7-36)
Serum immunoglobulin	Normal electrophoresis strip
Thyroid stimulating hormone	0.9 microU / mL (reference 0.4-5.0)

X-rays of hands: some minor degenerative change in right index proximal interphalangeal joint but otherwise unremarkable with no bony erosion or deformity

What is the cause for the patients pain?

<input type="checkbox"/>	Fibromyalgia
<input type="checkbox"/>	Systemic lupus erythematosus
<input type="checkbox"/>	Chronic regional pain syndrome
<input type="checkbox"/>	Generalised anxiety disorder
<input type="checkbox"/>	Depression

□ Question 12 of 94

An 82-year-old gentleman was referred to the outpatients rheumatology clinic by his GP. He presented to his GP six weeks ago complaining of significant shoulder girdle stiffness. He felt weak and lethargic and complained of malaise. He also complained of pain and stiffness in both wrists, but especially his right wrist. The stiffness was worst in the morning, lasting an hour before easing off with activity. A trial of ibuprofen 400mg TDS alleviated his symptoms partially. On systems review, he denied any further symptoms, including the absence of weight loss, respiratory and urinary symptoms. He denied losing weight. He had previously been well, with a past medical history comprising of osteoarthritis of his knee joints, asthma and hypertension. He had never smoked and consumed eight units of alcohol per week.

Examination revealed an elderly gentleman who was systemically well. His temperature was 37.4°C, heart rate 74 bpm, and blood pressure 138/78 mmHg. Examination of his musculoskeletal system revealed the presence of right wrist tenderness and slight swelling, as well as restricted active movements of his shoulders. Examination of his cardiovascular, respiratory, gastrointestinal and neurological systems was unremarkable.

Initial investigations by his GP revealed the following results:

ESR	55 mm/hr
CRP	58 mg/l
CPK	188 u/l (reference range 17-148)
PSA	2.6 ng/ml

Serum electrophoresis	normal clonal pattern
Rheumatoid factor	pending
Anti-CCP	pending
Full antibody screen	pending

Chest x-ray: normal heart and lung fields

Urine Bence Jones protein: negative

From the information so far, what is the most likely diagnosis?

	Paraneoplastic syndrome
	Late onset rheumatoid arthritis (RA)
	Polymyalgia rheumatica (PMR)
	Polymyositis
	Giant cell arteritis

□ Question 12 of 94

An 82-year-old gentleman was referred to the outpatients rheumatology clinic by his GP. He presented to his GP six weeks ago complaining of significant shoulder girdle stiffness. He felt weak and lethargic and complained of malaise. He also complained of pain and stiffness in both wrists, but especially his right wrist. The stiffness was worst in the morning, lasting an hour before easing off with activity. A trial of ibuprofen 400mg TDS alleviated his symptoms partially. On systems review, he denied any further symptoms, including the absence of weight loss, respiratory and urinary symptoms. He denied losing weight. He had previously been well, with a past medical history comprising of osteoarthritis of his knee joints, asthma and hypertension. He had never smoked and consumed eight units of alcohol per week.

Examination revealed an elderly gentleman who was systemically well. His temperature was 37.4°C, heart rate 74 bpm, and blood pressure 138/78 mmHg. Examination of his musculoskeletal system revealed the presence of right wrist tenderness and slight swelling, as well as restricted active movements of his shoulders. Examination of his cardiovascular, respiratory, gastrointestinal and neurological systems was unremarkable.

Initial investigations by his GP revealed the following results:

ESR	55 mm/hr
CRP	58 mg/l
CPK	188 u/l (reference range 17-148)
PSA	2.6 ng/ml

Serum electrophoresis	normal clonal pattern
Rheumatoid factor	pending
Anti-CCP	pending
Full antibody screen	pending

Chest x-ray: normal heart and lung fields

Urine Bence Jones protein: negative

From the information so far, what is the most likely diagnosis?

	Paraneoplastic syndrome
	Late onset rheumatoid arthritis (RA)
	Polymyalgia rheumatica (PMR)
	Polymyositis
	Giant cell arteritis

□ Question 13 of 94

A 60 year old woman attended her General Practitioner and reported a three month history of bilateral shoulder muscle and bilateral hip girdle aches and pain. She also experienced stiffness affecting these areas that lasted for up to two hours each morning. These symptoms were limiting her day to day activities and were unresponsive to simple analgesics.

The patient denied symptoms of headache, visual disturbance or jaw claudication. Intermittent episodes of dry mouth and dry eyes had been present for several years. There was no history of unexplained skin rashes. Past medical history included coeliac disease diagnosed twenty years previously that was well controlled on a gluten-free diet. The patient was a non-smoker and drank alcohol only occasionally.

Examination revealed mild muscular tenderness across the shoulder and hip girdles although with no other inflamed or tender joints. Cardiovascular and respiratory examination was unremarkable.

Blood tests requested by her GP demonstrated an elevated ESR of 65. A diagnosis of PMR was made and a course of 20 mg prednisolone daily prescribed. However 6 weeks later the patients symptoms had not significantly improved and she was referred to rheumatology clinic. Repeat blood tests and other investigations are listed below.

Haemoglobin	110 g / dL
White cell count	$8.9 \times 10^9/\text{L}$
Neutrophils	$7.8 \times 10^9/\text{L}$
Platelets	$456 \times 10^9/\text{L}$
Urea	6.2 mmol / L
Creatinine	87 micromol / L
Sodium	138 mmol / L
Potassium	4.1 mmol / L
Ferritin	180 ng / mL
Erythrocyte sedimentation rate	75 mm / h

Rheumatoid factor	Negative
Connective tissue ANA	Negative
Anti-CCP antibodies	58 EU (reference < 20)
Creatinine kinase	89 U / L (reference 5-130)

X-ray hands: minor degenerative change in multiple inter-phalangeal joints of both hands; no evidence of erosive arthropathy

What is correct diagnosis?

<input type="checkbox"/>	Polymyalgia rheumatica
<input type="checkbox"/>	Rheumatoid arthritis
<input type="checkbox"/>	Polymyositis
<input type="checkbox"/>	Sjorgren's syndrome
<input type="checkbox"/>	Systemic lupus erythematosus

□ Question 14 of 94

A 71-year-old man with a history of chronic obstructive pulmonary disease (COPD) is investigated for back pain. Over the past 10 years he has had numerous admissions for infective exacerbations of COPD and currently uses long-term oxygen therapy. The pain came on suddenly whilst he was at his local supermarket.

A MRI scan is requested:

What is the most likely underlying cause of the back pain?

	Osteomyelitis
	Multiple myeloma
	Pott's disease
	Metastatic lung cancer
	Osteoporosis

□ Question 15 of 94

A 62-year-old lady is seen in the rheumatology clinic. She was diagnosed with rheumatoid arthritis 16 years ago. Her symptoms were relatively well controlled with a combination of methotrexate 20mg once per week, folic acid 5mg once per week and azathioprine 100mg once per day until the last few months when she complained of increasing joint pain with stiffness. Since then her methotrexate dose was gradually titrated to the current dose of 25mg per week. She reported that her joints were less painful and stiff in the morning. Unfortunately, she was also complained of increasing tiredness with an increasing quantity of respiratory tract infections, requiring antibiotics twice in the last six months. She also noted that she bruised more easily of late.

Examination revealed a slender 62-year-old systemically well lady. She was haemodynamically normal and afebrile. Cardiovascular and respiratory examinations were unremarkable, and abdominal examination revealed a mass arising from the left upper quadrant. Clinical examination of her joints revealed no evidence of synovitis or swelling.

Routine blood investigations prior to attending clinic were as follows:

Hb	115 g/l
MCV	84 fl
Platelets	$82 \times 10^9/l$
WBC	$3.5 \times 10^9/l$
Neutrophils	$1.6 \times 10^9/l$
Lymphocytes	$1.0 \times 10^9/l$
Eosinophils	$0.9 \times 10^9/l$

Na ⁺	141 mmol/l
K ⁺	3.9 mmol/l
Urea	7.0 mmol/l
Creatinine	81 μ mol/l

Bilirubin	12 µmol/l
ALP	99 u/l
ALT	13 u/l
Albumin	39 g/l

What is the single most likely cause of the clinical and haematological abnormalities?

	Myelodysplastic syndrome
	Chronic lymphocytic leukaemia
	Marrow aplasia secondary to drug therapy
	Felty's syndrome
	Myelodysplasia

□ Question 16 of 94

A 47-year-old lady presented with a three-week history of pain in her fingers. She had noticed her hands were getting extremely cold when she went outside and turned a 'funny colour'. When she came back inside her hands were very painful as they began to warm up. She had managed in the past by wearing gloves outside but now had ulcers on her fingertips which she had never experienced before. She also complained of epigastric pain and had longstanding shortness of breath.

Her past medical history included pulmonary fibrosis and hypertension. Her medications included propranolol, amlodipine, simvastatin and omeprazole.

On examination the skin over her hands was dry and shiny and there was severe digital ulceration on three fingertips of the left hand. There was no exudate or erythema. The fingertips were dusky in colour and extremely tender. The skin over the upper arms and chest appeared normal. On auscultation of the lungs there were fine bibasal inspiratory crepitations which did not alter in character upon coughing. Heart sounds were normal with no added murmurs. There was a left ventricular heave

Which of the following is the most appropriate management plan for this lady?

	Start flucloxacillin and stop all anti-hypertensive medications
	Educate this lady about the use of gloves and hand-warmers and increase her amlodipine dose
	Stop amlodipine and refer for an urgent dermatology assessment
	Stop propranolol and admit for an iloprost infusion
	Start high dose oral prednisolone

□ Question 21 of 94

A 39-year-old lady presented to the emergency department acutely unwell with fever, weight loss and malaise. She had been finding it increasingly difficult to mobilise in recent weeks due to weakness in her right ankle. She had diarrhoea and was passing loose brown stool up to five times a day. She had a previous medical history of asthma and sinusitis. Her medications included a salbutamol inhaler, salmeterol inhaler, montelukast and intermittent courses of prednisolone and antibiotics as required.

On examination, she appeared unwell, had petechial purpura in the nail beds of her fingers and on her feet, expiratory wheeze on auscultation of her chest, a soft abdomen with no palpable masses and weakness of dorsiflexion of her right ankle. Her temperature was 37.4 degrees Celsius, her pulse was 115 beats per minute and regular, her blood pressure was 140/95 mmHg, her respiratory rate was 24 breaths per minute and her oxygen saturations were 94% on room air.

Investigations:

Urine dip: blood++, protein+

Haemoglobin	95 g/L
White cell count	$23.6 \times 10^9 /L$
Platelet Count	$181 \times 10^9 /L$
Neutrophils	$12.3 \times 10^9 /L$
Eosinophils	$9.6 \times 10^9 /L$
Basophils	$0.2 \times 10^9 /L$
Lymphocytes	$1 \times 10^9 /L$
Monocytes	$0.5 \times 10^9 /L$
Erythrocyte sedimentation rate	65mm/hr
INR	0.9

Serum sodium	138mmol/L
--------------	-----------

Serum potassium	4.6mmol/L
Serum urea	15.4mmol/L
Serum creatinine	220micromol/L

Antinuclear antibody	negative
C-terminus antineutrophil cytoplasmic antibodies	negative
Myeloperoxidase anti-neutrophil cytoplasmic antibodies	positive

What is the most likely diagnosis?

<input type="radio"/>	Infective endocarditis
<input type="radio"/>	Wegener's granulomatosis
<input type="radio"/>	E.Coli gastroenteritis
<input type="radio"/>	Churg-Strauss syndrome
<input type="radio"/>	Crohn's disease

A 39-year-old lady presented with a 2-week history of increasing cough and was passing loose brown stools. Her medications included a statin and antibiotics as required.

On examination, she appeared well. There was no wheeze on auscultation of her lungs. Her temperature was 38.5°C, her blood pressure was 140/95 mmHg, her respiratory rate was 20/min.

Investigations:

Urine dip: blood++, protein+

Haemoglobin	
White cell count	23.6 x10 ⁹ /L
Platelet Count	181x10 ⁹ /L
Neutrophils	12.3 x10 ⁹ /L
Eosinophils	9.6 x10 ⁹ /L
Basophils	0.2 x10 ⁹ /L
Lymphocytes	1 x10 ⁹ /L
Monocytes	0.5 x10 ⁹ /L
Erythrocyte sedimentation rate	65mm/hr
INR	0.9

Serum sodium	138mmol/L
--------------	-----------

Serum potassium	4.6mmol/L
Serum urea	15.4mmol/L
Serum creatinine	220micromol/L

Antinuclear antibody	negative
C-terminus antineutrophil cytoplasmic antibodies	negative
Myeloperoxidase anti-neutrophil cytoplasmic antibodies	positive

What is the most likely diagnosis?

	Infective endocarditis
	Wegener's granulomatosis
	E.Coli gastroenteritis
	Churg-Strauss syndrome
	Crohn's disease

Question 23 of 94

□ □

A 41-year-old woman presents with tightening of fingers, mild difficulty swallowing, and mild shortness of breath on exertion. She takes pantoprazole for reflux. On examination there is tightening of skin in her fingers, however the rest of the skin is normal. Her joints are not inflamed. The rest of her examination was normal (including chest examination). Her chest X-ray is also normal. There is mild decrease in DLCO on lung function tests. Which of the following antibodies are indicative of the underlying diagnosis?

	Anti-Scl-70 antibody
	Anti-dsDNA antibody
	Rh factor antibody
	Anti-centromere antibody
	Anti-Jo-1 antibody

□ Question 29 of 94

A 32-year-old gentleman presented to his GP with an 8-week history of debilitating pain in his oral cavity and in his groin area. He had presented on numerous occasions to his GP with episodes of tiredness and non-specific malaise which each time was put down to non-specific viral illness. Eight months ago he was investigated by a gastroenterologist having presented with bloody diarrhoea and abdominal pain. He was diagnosed with a non-specific colitis of unknown origin which resolved spontaneously. He also suffered a solitary DVT of his left leg 6 years ago which was treated with oral anticoagulation. He smoked 20 cigarettes per day and consumed 20 units of alcohol per week. He was on no regular medication. Upon specific questioning, he denied joint pain or swelling. He also denied the presence of back pain. He was unaware of any family history as he was adopted from birth.

On examination, he appeared pale. His heart rate was 88 and blood pressure 118/78 mmHg. Examination of his cardiovascular system was unremarkable. Examination of his abdomen was likewise unremarkable. Examination of his oral mucosa revealed the presence of multiple aphthous ulceration. Examination of his external genitalia likewise revealed the presence of multiple shallow ulcers within his groin region. Examination of his joints was unremarkable.

Initial investigations revealed the following results:

Hb	139 g/l
Platelets	$333 \times 10^9/l$
WBC	$5.1 \times 10^9/l$
ESR	22 mm/hr
CRP	28 mg/l
Rheumatoid factor	negative
Anti CCP	negative
ANA	negative
HLA B27	positive

What is the most likely underlying diagnosis?

	Seronegative arthritis
	Disseminated gonococcal infection
	Crohn's disease
	Coeliac disease
	Behcet's syndrome

Dashboard

Overall score: 0%

□ Question 31 of 94

A 45-year-old Caucasian man presents with an acutely painful left knee. He is unable to mobilise due to the pain and swelling. Prior to this episode, the patient states that he is generally active, often enjoying a round of golf every Sunday. Last week he had a minor fall onto both knees whilst clearing out the garage. He puts his current symptoms down to general aches and pain of 'old age'.

The patient has also noticed that he is waking up more often in the night to pass urine. His wife has noticed that he is looking more 'tanned' despite them not going abroad on holiday this year. On further questioning, he admits to drinking 5-6 pints of ale per week. He is a non-smoker.

On examination on the Medical Assessment Unit you note significant left sided knee swelling. The joint is hot and tender to touch. There is no evidence of any surrounding skin changes.

His random glucose is measured at 18mmol/L.

Further blood tests are shown below:

Hb	138 g/l
Platelets	$120 \times 10^9/l$
WBC	$7.0 \times 10^9/l$

Na ⁺	138 mmol/l
K ⁺	4.0 mmol/l
Urea	6.2 mmol/l
Creatinine	88 μ mol/l
CRP	72 mg/L

What is the most likely cause of his acutely swollen knee?

--	--

	Pseudogout
	Ruptured Baker's cyst
	Septic arthritis
	Gout
	Haemarthrosis

□ Question 32 of 94

A 35-year-old lady with diffuse systemic sclerosis attends the rheumatology clinic. She has had worsening arthralgia over the last 2 months, mainly in the hands and feet. She does not complain of any other symptoms.

On examination her blood pressure is 161/94 mmHg, her heart rate is 90 beats per minute and her oxygen saturations are 96% on room air. She has sclerodactyly and tender small joints of the hands and feet with mild swelling. The hands are pale and cool. Her chest is clear.

Her blood tests are as follows:

Hb	110 g/l	Na ⁺	136 mmol/l	Bilirubin	5 µmol/l
Platelets	210 * 10 ⁹ /l	K ⁺	4.7 mmol/l	ALP	90 u/l
WBC	10 * 10 ⁹ /l	Urea	5 mmol/l	ALT	21 u/l
Neuts	7 * 10 ⁹ /l	Creatinine	89 µmol/l	γGT	30 u/l
Lymphs	2.5 * 10 ⁹ /l	ESR	99 mm/h	Albumin	32 g/l

Which drug should be used with caution in this patient?

	Tacrolimus
	Azathioprine
	Methotrexate
	Mycophenolate mofetil
	Prednisolone

Overall score: **0%**

□ Question 35 of 94

A 55-year-old man is referred to rheumatology for management of severe tophaceous gout. The patient had been experiencing intermittent gout attacks over the previous few years, typically affecting the first metatarsophalangeal joints of both feet. However, during the last two months the patient had developed inflammation of multiple small joints of his hand preventing the patient from continuing his work as a train driver. A trial of Colchicine prescribed by the patient's General Practitioner had been discontinued after the patient experienced severe diarrhoea. Past medical history included an upper GI bleed secondary to a duodenal ulcer six months previously.

Examination demonstrated severe asymmetrical inflammation of multiple metacarpalphalangeal, distal interphalangeal and proximal interphalangeal joints across both hands. Yellow-white tophi were present across the inflamed joints. Blood tests taken prior to clinic attendance are listed below.

Hb	15.2 g/dl
Platelets	$265 \times 10^9/l$
WBC	$6.5 \times 10^9/l$

Na ⁺	134 mmol/l
K ⁺	4.2 mmol/l
Urea	9.5 mmol/l
Creatinine	175 μ mol/l
eGFR	62 ml/min
Urate	370 μ mol/l

What is the best treatment for this patient's acute gout?

	Intra-articular steroid injection
	Naproxen

	Allopurinol
	Febuxostat
	Short course prednisolone

Dashboard

Overall score: **0%**

Question 36 of 94

A 35-year-old female with a past medical history of sinusitis and asthma for four years is admitted with a pyrexia, worsening of dyspnoea and ankle swelling. Two weeks prior to admission she had noticed blood streaks were present in her sputum.

On examination she had widespread wheeze and bi-basal crepitations on auscultation of her chest. Her saturations are 94% without oxygen but come up to 99% after treatment with salbutamol and ipratropium bromide nebulisers and oxygen therapy.

She has a heart rate of 112 beats per minute, normal heart sounds and a raised JVP. She has pitting oedema up to her knees. Examination of her abdominal system is unremarkable.

Haemoglobin	102 g/L
White cell count	$11.2 \times 10^9/\text{L}$
Eosinophil count	$1.9 \times 10^9/\text{L}$
Platelet count	$478 \times 10^9/\text{L}$
International normalised ratio	1.3

Serum sodium	135 mmol/L
Serum potassium	5.5 mmol/L
Serum urea	21 mmol/L
Serum creatinine	211 mol/L
CRP	22 mg/l
Blood cultures	Coagulase-negative staphylococci
ANCA positive	immunostaining awaited

Urine dip- positive for protein and blood

CXR: Bi-basal non specific shadowing

What is the most likely diagnosis?

	Churg Strauss syndrome
	Systematic Inflammatory Response Syndrome
	Systematic Lupus Erythematosus
	Wegeners granulamatosiis
	Microscopic polyangiitis

□ Question 37 of 94

A 65 year old man presented to his General Practitioner with a 3 month history of bilateral shoulder aches and pains. The symptoms were associated with stiffness in the mornings taking up to two hours to resolve after waking. The patient denied any symptoms of headache, jaw claudication or visual disturbance. The patient had no symptoms of dry eyes or mouth, no skin or hair changes, no weight loss and no fevers.

Past medical history included hypertension and chronic obstructive pulmonary disease. Regular medications included ramipril, simvastatin and inhaled salbutamol as required. The patient was an ex-smoker who drank 25 units of alcohol per week. The patient had recently retired having spent his working life as a train driver.

Examination did not reveal any inflamed joints excepting slight tenderness across the shoulder girdle. There was no evidence of scalp tenderness. Cardiovascular and respiratory examination was unremarkable.

Investigations requested by the General Practitioner are listed below.

Haemoglobin	134 g / dL
White cell count	$7.5 \times 10^9/\text{L}$
Neutrophils	$6.0 \times 10^9/\text{L}$
Platelets	$356 \times 10^9/\text{L}$
Urea	8.9 mmol / L
Creatinine	110 micromol / L
Sodium	132 mmol / L
Potassium	4.9 mmol / L
Erythrocyte sedimentation rate	85 mm / h
Rheumatoid factor	Negative
Creatinine kinase	121 U / L (reference 5-130)
Calcium (adjusted)	2.25 mmol / L (reference 2.18-2.58)

Alkaline phosphatase	67 U / L (reference 35-100)
Thyroid stimulating hormone	2.5 microU / L
Protein electrophoresis	Normal

What is the appropriate next management step for this patient?

	Stop statin therapy and review in 6 weeks
	Ultrasound study of shoulders and hips
	Referral for specialist rheumatology opinion
	Prednisolone 15 mg daily with dose tapering over 2 years
	Prednisolone 40 mg daily with dose tapering over 1 year

□ Question 38 of 94

A 35-year-old woman presents to rheumatology clinic with a 2-month history of symmetrical swelling of the ankles and fingers. She also complains of joint pain and stiffness. The stiffness is primarily worse in the early morning and eases with use. Apart from a recent sore throat, she is otherwise well. She has a family history of type 1 diabetes mellitus. She does not take any prescribed medication but has found herself relying on over-the-counter analgesics to get through the day.

On examination, she has bilateral swelling of the index, ring and middle fingers and bilateral ankle swelling. She has a full range of movement in the fingers, wrists and ankles. There is marked swelling and tenderness to palpation at the distal interphalangeal joints in the index, middle and ring fingers on both sides. There are no skin changes, but yellowing and pitting of the nails are noted.

Blood tests show:

Hb	11.1 g/dl
Platelets	$305 \times 10^9/l$
WBC	$7.8 \times 10^9/l$

Na ⁺	141 mmol/l
K ⁺	4.2 mmol/l
Urea	5.8 mmol/l
Creatinine	64 μ mol/l

Bilirubin	13 μ mol/l
ALP	83 u/l
ALT	15 u/l
ESR	50mm/hr
CRP	39 mg/L

Rheumatoid factor	negative

Hand X-ray shows mild erosion at the distal interphalangeal joints of the index, middle and ring fingers on both hands.

What is the diagnosis?

	Rheumatoid arthritis
	Reiters syndrome
	Ankylosing spondylitis
	Yellow nail syndrome
	Psoriatic arthritis

□ Question 41 of 94

A 77-year-old lady is reviewed in the Rheumatology Clinic with a 4-week history of malaise and bilateral hip pain.

The pain is poorly localised and affects the anterior and posterior aspects of the pelvis as well as the upper thighs. It is typically worse in the mornings and associated with feelings of stiffness that take several hours to improve.

She also reports the recent onset of a right-sided headache, which is constant and has been present for the past 2 weeks. 24 hours ago, she developed an episode of transient visual darkening although she is unable to recall which eye was affected.

Her past medical history is remarkable for hypertension and hypothyroidism. Her regular medications include amlodipine 5mg once daily and levothyroxine 75 micrograms once daily.

On examination, her visual acuity is 6/9 in both eyes. Her temperature is 37.3°C, her pulse is 73bpm and her blood pressure is 143/81mmHg. Neurological examination reveals no focal abnormality although the pulsation of her right temporal artery is difficult to feel.

Her blood results are as follows:

Hb	124 g/l	Na ⁺	141 mmol/l
Platelets	444 * 10 ⁹ /l	K ⁺	3.9 mmol/l
WBC	11.2 * 10 ⁹ /l	Urea	4.3 mmol/l
Neuts	8.1 * 10 ⁹ /l	Creatinine	78 µmol/l
Lymphs	2.3 * 10 ⁹ /l	CRP	102 mg/l
Eosin	0.02 * 10 ⁹ /l		

A temporal artery biopsy is performed and a 0.8cm sample is obtained. It is reported as being 'negative for giant cell arteritis (GCA)'.

What is the most appropriate treatment strategy?

	IV methylprednisolone 1 gram once daily
	Prednisolone 15mg once daily
	Amitriptyline 10mg once daily
	Explanation, reassurance and referral to physiotherapy for graded aerobic exercise
	Prednisolone 60mg once daily

□ Question 42 of 94

□ □

A 30 year old lady with rheumatoid arthritis, presents feeling unwell. She has felt lethargic for the last two days and over the last 24 hours has developed a severe sore throat. She has been on the following prescription for the last six months; paracetamol 1g QDS, naproxen 500mg PRN, methotrexate 15mg once weekly, folic acid 5mg once weekly and prednisolone 5mg OD. She is septic on examination with observations as follows: respiratory rate 26/min, heart rate 120/min, blood pressure 100/67mmHg, temperature 37.9°C. She is tolerating oral fluids and small amounts of food. Adequate fluid resuscitation and antibiotics are started. With regards to her regular medications what should be done?

	Hold methotrexate and half dose of prednisolone
	Hold methotrexate and increase prednisolone to 10mg once daily
	Half dose of methotrexate and increase prednisolone to 10mg once daily
	Refer to rheumatology for urgent review
	Hold methotrexate and start IV methylprednisolone

□ Question 43 of 94

A 52-year-old man presents with lethargy and reduced sensation in both feet. He reports a 2 month history of fevers and 4kg weight loss. He also reports intermittent testicular pain.

On examination there is livedo reticularis on both legs and reduced light touch and pain sensation on both feet.

Blood tests reveal:

Hb	116 g/l	Na ¹³⁷	# mmol/l	Bilirubin	18 µmol/l
Platelets	487 * 10 ⁹ /l	K ⁺	4.8 mmol/l	ALP	92 u/l
WBC	8.3 * 10 ⁹ /l	Urea	12.8 mmol/l	ALT	102 u/l
Neuts	6.3 * 10 ⁹ /l	Creatinine	182 µmol/l	γGT	16 u/l
MCV	89 fL	ESR	78mm/hr	Albumin	35 g/l

What is the most likely diagnosis?

	Cryoglobulinaemia
	Granulomatosis with polyangiitis
	Eosinophilic granulomatosis with polyangiitis
	Polyarteritis nodosa
	Microscopic polyangiitis

Question 44 of 94

□ □

A 32 year old female with known rheumatoid arthritis presents to clinic and would like some advice. She would like to start a family with her partner. Her rheumatoid arthritis is current well-controlled on methotrexate and sulphasalazine, she has not required changing of doses for 2 years. She is reluctant to stop medications unless she has to, she had a number of flares when doses were reduced 3 years ago. What would you advice regarding her plans for pregnancy?

	She should reconsider her plans for pregnancy. Stopping medications would make her disease uncontrollable and continuing medications will affect her child
	Continue sulphasalazine and methotrexate
	Stop sulphasalazine, continue methotrexate
	Continue sulphasalazine and stop methotrexate
	Stop both sulphasalazine and methotrexate

Dashboard

☐ Question 45 of 94

A 62-year-old man with a diagnosis of Paget's disease is seen in clinic with a two month history of worsening bone pain, mainly in his left leg. His medications include paracetamol, ibuprofen, and alendronate.

Examination reveals marked deformity of the long bones, particularly the left tibia.

Blood tests:

Calcium	2.40 mmol/L (2.25-2.5)
Albumin	37g/L (34-54)
Corrected calcium	2.50 mmol/L (2.25-2.5)
Alkaline phosphatase	484 U/L (45-105)
Alanine transaminase	27 U/L (5-35)

What is the next stage in the treatment of this patient?

<input type="checkbox"/>	Cholecalciferol
<input type="checkbox"/>	Surgery
<input type="checkbox"/>	Calcitonin

□ Question 47 of 94

A 73-year-old woman attends rheumatology clinic for review of her osteoporosis treatment. The patient had been diagnosed with osteoporosis five years previously on a DEXA scan performed after she had sustained a fractured right neck of femur. Since the time of diagnosis, the patient had been receiving treatment with alendronic acid (70 mg weekly).

During clinic review, the patient reported taking her alendronic acid as prescribed without any associated side effects. A review of her past medical history revealed that the patient had sustained a left distal radius fracture the previous year following a trip at home. In addition, the patient had suffered from a deep vein thrombosis in her right leg three years before precipitated by a trans-continental flight and had been anti-coagulated with warfarin for six months.

The patient was a smoker (10 cigarettes per day) and also consumed around 20 units of alcohol per week. Her mother had suffered a fractured neck of femur at the age of 80. The patient had never been diagnosed with rheumatoid arthritis and had no significant exposure to corticosteroid treatment.

Clinical examination of the patient demonstrated no loss of height since previous measurement five years previously. There was no tenderness on palpation of the thoracic or lumbar spine.

Height	175 cm
Weight	95 kg
Femoral neck BMD (5 years previously)	T - 2.7
Femoral neck BMD (present day)	T - 2.9
FRAX 10-year probability of major osteoporotic fracture	60 %
FRAX 10-year probability of hip fracture	50 %

What is the appropriate management of the patient's osteoporosis?

	Stop treatment with alendronic acid and start treatment with denosumab
	Stop treatment with alendronic acid and start treatment with strontium ranelate

	Continue treatment with alendronic acid with repeat DEXA scan in five years
	Continue treatment with alendronic acid with repeat DEXA scan in two years
	Stop treatment with alendronic acid with repeat DEXA scan in two years

□ Question 49 of 94

A 39-year-old lady is referred to the acute medical clinic. She presents with a 3 weeks history of worsening shortness of breath and left-sided pleuritic chest pain. She denies a cough, sputum or haemoptysis. Her exercise tolerance, previously unlimited is now down to approximately 100 yards. She denies any weight loss but admits that she has been feeling hot and having fevers fairly regularly over the last 6 months. In addition, she complains of aches and pains in her knees and wrists for which she has been taking ibuprofen with reasonable effect. She is normally fit and well and on no regular medication. She is a non-smoker and drinks alcohol socially. She works as a secretary.

On examination she has a BMI of 21 kg/m², her temperature is 37.4°C and her blood pressure is 128/67 mmHg with a heart rate of 76/min. Her respiratory rate is 19/min and her oxygen saturations are 96% on air. She has some submandibular and sublingual lymphadenopathy. She has reduced air entry at her left base with a stony dull percussion note. Examination of her cardiovascular and abdominal systems are unremarkable, as is an examination of her wrists and knees. You notice she has a salmon pink rash across her chest and upon questioning she admits that it has been there for the last few weeks.

Her blood tests show:

Hb	109 g/l
Platelets	523 * 10 ⁹ /l
WBC	19.3 * 10 ⁹ /l
Neuts	14.5 * 10 ⁹ /l
ESR	30 mm/hr
Ferritin	2000 µg/l

Na ⁺	136 mmol/l
K ⁺	3.6 mmol/l
Urea	3.1 mmol/l
Creatinine	70 µmol/l

CRP	45 mg/l
-----	---------

Bilirubin	18 µmol/l
ALP	119 u/l
ALT	67 u/l
Albumin	34 g/l

Rheumatoid factor	negative
ANA	negative
Anti-histone antibodies	negative

She has a chest x-ray which shows a medium-sized left pleural effusion.

What is the likely cause of her symptoms?

<input type="checkbox"/>	Non-Hodgkin's lymphoma
<input type="checkbox"/>	Small cell lung cancer
<input type="checkbox"/>	Adult onset Stills disease
<input type="checkbox"/>	Rheumatoid arthritis
<input type="checkbox"/>	Mixed connective tissue disease

In addition, she complains of aches and pains in her knees and wrists for which she has been taking ibuprofen with reasonable effect. She is normally fit and well and on no regular medication. She is a non-smoker and drinks alcohol socially. She works as a secretary.

On examination she has a BMI of 21 kg/m², her temperature is 37.4°C and her blood pressure is 128/67 mmHg with a heart rate of 76/min. Her respiratory rate is 19/min and her oxygen saturations are 96% on air. She has some submandibular and sublingual lymphadenopathy. She has reduced air entry at her left base with a stony dull percussion note. Examination of her cardiovascular and abdominal systems are unremarkable, as is an examination of her wrists and knees. You notice she has a salmon pink rash across her chest and upon questioning she admits that it has been there for the last few weeks.

Her blood tests show:

Hb	109 g/l
Platelets	523 * 10 ⁹ /l
WBC	19.3 * 10 ⁹ /l
Neuts	14.5 * 10 ⁹ /l
ESR	30 mm/hr
Ferritin	2000 µg/l

Na ⁺	136 mmol/l
K ⁺	3.6 mmol/l
Urea	3.1 mmol/l
Creatinine	70 µmol/l

CRP	45 mg/l
-----	---------

Bilirubin	18 µmol/l
ALP	119 u/l
ALT	67 u/l
Albumin	34 g/l

Rheumatoid factor	negative
ANA	negative
Anti-histone antibodies	negative

She has a chest x-ray which shows a medium-sized left pleural effusion.

What is the likely cause of her symptoms?

	Non-Hodgkin's lymphoma
	Small cell lung cancer
	Adult onset Stills disease
	Rheumatoid arthritis
	Mixed connective tissue disease

Question 50 of 94

A 69-year-old man with a history of rheumatoid arthritis well controlled on methotrexate presents with gradual pain and swelling in his wrists and ankles.

The pain is described as a dull ache that is intermittent, often worse in the evenings. There is associated swelling which can sometimes feel warm. He has tried regular paracetamol but this has had limited effect.

He also describes a chronic cough and shortness of breath on exertion for the past 6 months that he has not mentioned to his GP. There has been no haemoptysis and he denies any fevers. His wife has noticed that he has been losing weight recently.

He has a past medical history of rheumatoid arthritis, hypertension, hypercholesterolaemia and type 2 diabetes mellitus. He currently takes methotrexate weekly, folic acid 5mg weekly, ramipril 5mg, simvastatin 20mg at night, metformin 500mg three times a day and paracetamol 1g four times daily.

He is a retired accountant and a current smoker with a 50 pack year smoking history. He drinks approximately 30 units of beer a week. He denies any recent foreign travel.

On examination, he is cachectic and short of breath on exertion. His pulse is 80/min and regular, blood pressure 140/93 mmHg, oxygen saturations of 93% on air. He has marked fingernail clubbing. Examination of his wrists reveals slightly swollen and tender joints. Swan neck and ulnar deviation deformities are noted in both hands. Other than his wrists, no other joint abnormalities are detected. Examination of the peripheral nervous system is normal.

Examination of his chest is normal with no focal consolidation.

Initial bloods are as follows:

Na ⁺	134 mmol/L
K ⁺	3.9 mmol/L
Urea	7.8 mmol/L
Creatinine	105 µmol/L
Hb	100 g/L

WBC	6.0x10 ⁹ /L
Platelets	200x10 ⁹ /L
LFTs	Normal
Serum uric acid	410 µmol/L
CRP	12 mg/L

Chest X-ray reveals a discrete opacification at the periphery of the right middle lobe.

What is the most likely cause of his joint pains?

<input type="checkbox"/>	Rheumatoid arthritis flare
<input type="checkbox"/>	Gout
<input type="checkbox"/>	Hypertrophic pulmonary osteoarthropathy secondary to bronchogenic carcinoma
<input type="checkbox"/>	Reiter's syndrome
<input type="checkbox"/>	Osteoarthritis

Question 51 of 94

□ □

A 28-year-old woman with systemic lupus erythematosus attends the pre-conception clinic. She would like some advice regarding her medications prior to getting pregnant. She has never been pregnant before and her lupus has been stable on her current medications: mycophenolate and hydroxychloroquine for over 12 months. She also has asthma, which is well controlled with beclomethasone and salbutamol inhalers, and she takes regular omeprazole for gastro-oesophageal reflux.

What is the most appropriate medication amendment?

	Half omeprazole dose
	Stop beclomethasone inhaler
	Stop hydroxychloroquine
	Add ramipril 1.25mg
	Change mycophenolate to azathioprine

Question 53 of 94

A 75 year old male presents to A&E with two episodes of loss of consciousness over the last 48 hours. Both episode were witnessed by his wife, onset while sitting in his chair at home, without any witnessed limb jerking, urinary incontinence or tongue biting. He denies any chest pain or shortness of breath normally but reports gradually being able to walk increasingly shorter distances, which he attributed to old age. He has no other significant past medical history, lives with his wife and is a lifelong non-smoker. On examination, he has a significant thoracic kyphosis. On flexion of the lower back, the marked distance increased from 15 cm to 18 cm. He also has a poverty of spinal lateral flexion and bilateral spinal rotation. His cardiovascular examination reveals heart sounds I and II with an early diastolic murmur. Respiratory examination reveals fine inspiratory crackles at both apices. His lying and standing blood pressures are unremarkable. A CT head demonstrated only mild microangiopathic disease. The patient is currently comfortable and alert, requesting to go home. He is attached to cardiac telemetry. What do you expect his ECG to show?

	Sinus bradycardia
	Trigeminy
	Fast atrial fibrillation with ventricular response greater than 100
	Atrial flutter
	Bradycardia with 1st degree heart block

□ Question 55 of 94

A 65-year-old man was referred to rheumatology for advice regarding the management of his gout. The patient had suffered intermittent episodes of inflammation of the first metatarsophalangeal joint of both feet over the past ten years. The frequency of these episodes had been increasing, with 6 episodes in the past year. In addition, the patient's right knee had recently become inflamed with microscopy of synovial aspirate demonstrating needle shaped crystals with negative birefringence.

Colchicine and NSAIDs had been used effectively to provide symptomatic relief to the patient during an acute attack. Allopurinol had been previously trialled as prophylaxis at a dose of 200 mg daily, although was stopped after the patient's renal function was noted to have deteriorated after allopurinol was initiated. Lifestyle modifications have also been attempted.

Other medical problems included type 2 diabetes, hypertension, hypercholesterolaemia and chronic renal failure. Regular medications were ramipril, metformin and simvastatin.

On examination the patient was noted to be obese without evidence of current joint inflammation. Tophi were noted on examination of the patient's ears. Blood tests taken prior to clinic attendance are listed below.

Hb	16.5 g/dl
Platelets	$150 \times 10^9/l$
WBC	$8.6 \times 10^9/l$

Na ⁺	137 mmol/l
K ⁺	4.7 mmol/l
Urea	11.2 mmol/l
Creatinine	190 μ mol/l
eGFR	45 ml/min
Calcium (adjusted)	2.3 mmol/l
Urate	395 μ mol/l

What is the best strategy for gout prophylaxis in this patient?

	Prednisolone 10 mg daily
	Colchicine
	Febuxostat
	Naproxen
	Reduced dose allopurinol

□ Question 58 of 94

A 37 year old woman with known rheumatoid arthritis was reviewed at her annual follow-up at rheumatology clinic. The diagnosis of rheumatoid arthritis had been made ten years previously after the patient experienced severe inflammation of her meta-carpal phalangeal joints of both hands. Symptoms had been controlled with an initial reducing course of oral steroids and had been subsequently maintained on 15 mg of subcutaneous methotrexate weekly. She had experience one significant flare of her symptoms 18 months previously that had necessitated a single intra-muscular dose of corticosteroids.

On this occasion the patient reported no further swelling, pain or redness of the joints of her hands or other joints. She did report however that over the past 6 months she had experienced on-going severe pains throughout her body. In addition, she had been feeling tired and lethargic and had been finding it hard to concentrate on her work at as a computer programmer. She denied any history of skin rashes, photosensitivity, hair loss, swallowing difficulties or dry eyes and she had not lost any weight.

Examination did not demonstrate any evidence of active synovitis. A minor ulnar deviation of the digits of both hands was noted which the patient denied caused her any functional impairment. The patient was noted to be tender on palpation of the muscles of her arms, legs and paraspinal muscles. However, there was no associated muscle weakness with patient able to rise unaided from a chair without using the assistance of her arms. There was no thickening of the skin of the hands or face. Cardiovascular, respiratory and abdominal examination was unremarkable and there were no skin rashes.

Investigations requested following clinic review are listed below.

Haemoglobin	13.4 g / dL
White cell count	$6.6 \times 10^9/l$
Platelets	$198 \times 10^9/l$
Sodium	139 mmol / L
Potassium	4.3 mmol / L
Urea	4.8 mmol / L
Creatinine	75 micromol / L

Erythrocyte sedimentation rate	15 mm / h
Rheumatoid factor	Positive
Anti-nuclear antigen	Negative
Anti-citrullinated protein antibodies	37 units (reference < 20)

What is the likely cause of the patients new symptoms?

	Flare of rheumatoid arthritis
	Mixed connective tissue disease
	Chronic regional pain syndrome
	Inclusion body myositis
	Fibromyalgia

Dashboard

Overall score: 0%

□ Question 59 of 94

A 67-year-old female presented to the accident and emergency department with severe headache and shortness of breath for the last six hours followed by seizures which occurred twice during the last hour.

The patient is a known case of diffuse cutaneous systemic sclerosis diagnosed two years ago and she is on steroids and cyclophosphamide.

On examination, she looks ill, agitated and dyspnoeic. Her pulse rate is 100 beats per minute, regular and her blood pressure is 220/110 mmHg.

Her JVP is raised, there is a gallop rhythm and bilateral basal crackles. There is lower limb oedema and brisk reflexes.

Fundoscopy showed grade 3 hypertensive retinopathy.

Investigations done two weeks previously showed:

Serum sodium	140 mmol/L
Serum potassium	5.7 mmol/L
Serum urea	17 mmol/L
Serum creatinine	250 mol/L
Urinalysis	protein ++, blood ++

What is the most appropriate immediate treatment to lower her blood pressure?

	IV sodium nitroprusside
	IV labetalol
	Oral ACE inhibitor

	IV hydralazine
	Nitrate infusion

A 34-year-old man presents with back pain and leg weakness. This has been getting worse for the past two months and he now complains that he is 'bent over'. Over the past three months he describes feeling generally unwell, with a poor appetite and night sweats.

His past medical history includes hypothyroidism. He emigrated from Bangladesh around 6 months ago.

On examination he has a kyphosis. He is most tender over the lower part of the thoracic spine. Neurological examination of his lower limbs demonstrates reduced power in both legs.

A lumbar spinal film is shown below:

Question 62 of 94

□ □

A 40-year-old woman is seen in an outpatient rheumatology clinic. She was diagnosed with Systemic lupus erythematosus 5 years previously when she has presented with fatigue, anaemia and a rash. She also has a past medical history of hypertension, gout and psoriasis.

She had noticed that the joints in her hands were becoming deformed, however, she was able to complete day to day task without any functional impairment and denied pain in the affected joints.

On examination, she had symmetrical marked reducible ulnar subluxation and deviation at the MCP joints. X-rays of her hands showed no erosions.

What is the most likely diagnosis?

	Jaccoud's arthropathy
	Rheumatoid arthritis
	Gout
	Psoriatic arthritis
	Sarcoid arthropathy

□ Question 64 of 94

□ □

A 55-year-old woman presents for review. Her mother has just been discharged after suffering a hip fracture. She is concerned that she may have 'inherited' osteoporosis and is asking what she should do. She has no significant past medical history of note, takes no regular medication and has never sustained any fractures. She smokes around 20 cigarettes per day and drinks about 3-4 units of alcohol per day.

What is the most appropriate course of action?

	Arrange bone mineral density measurement (DEXA scan)
	Reassure her that assessment of fragility fracture risk does not need to be done until 65 years
	Refer her to the genetics team for a risk assessment
	Start first-line bone protection (i.e. ensure calcium/vitamin D replete + oral bisphosphonate)
	Use the FRAX tool

Dashboard

Overall score: 0%

□ Question 69 of 94

A 27 year old male presents after recently returning from Bangladesh with 2 weeks of daily spiking fever, a new rash on his foot and pain on bending his knees or closing his hands. He also reports lumps and bumps on his neck that he thinks is new. He denies any cough or weight loss. He has no other past medical history and is unaware of any unwell family members. On examination, his temperature is 39.2 degrees. You note a maculopapular rash on his left sole and face. His knees and wrists are swollen and tender. His chest and cardiovascular examination are unremarkable, his abdomen is soft. However, you note a 12cm splenomegaly. His serum tests demonstrate:

Hb	12.7 g/dl
Platelets	450 * 10 ⁹ /l
WBC	17.0 * 10 ⁹ /l
Neuts	11.0 * 10 ⁹ /l

Na ⁺	138 mmol/l
K ⁺	3.5 mmol/l
Urea	7.8 mmol/l
Creatinine	70 µmol/l

CRP	30 mg/l
Ferritin	2000 µg/l
ALP	250 u/l
ALT	160 u/l
ANA	negative
dsDNA	negative

His chest radiograph appears unremarkable with no focal consolidation. A first induced sputum is negative for acid fast bacilli. What is the diagnosis?

	Miliary tuberculosis
	Adult onset Stills disease
	Reactive arthritis post-travellers diarrhoea
	Porphyria cutanea tarda
	Systemic lupus erythematosus

Dashboard

Question 71 of 94

□ □

A 25-year-old woman with rheumatoid arthritis has returned to clinic complaining of a loss of taste sensation. Over the last few months, her early morning stiffness has been causing more problems and she also has been troubled by pain in both knees even after taking paracetamol and naproxen.

She was last reviewed one month ago and since then her joint stiffness and pain has improved slightly. On examination, there is a good range of movement in the knees. Her mucous membranes are moist and there are no ulcers in the mouth. Which of the following is most likely responsible?

	Anaemia of chronic disease
	Recent dose increase of hydroxychloroquine
	Associated Sjogren's syndrome
	Addition of penicillamine to her regimen

□ Question 71 of 94

A 25-year-old woman with rheumatoid arthritis has returned to clinic complaining of a loss of taste sensation. Over the last few months, her early morning stiffness has been causing more problems and she also has been troubled by pain in both knees even after taking paracetamol and naproxen.

She was last reviewed one month ago and since then her joint stiffness and pain has improved slightly. On examination, there is a good range of movement in the knees. Her mucous membranes are moist and there are no ulcers in the mouth. Which of the following is most likely responsible?

	Anaemia of chronic disease
	Recent dose increase of hydroxychloroquine
	Associated Sjogren's syndrome
	Addition of penicillamine to her regimen
	Chronic use of tramadol to control her joint pain

Dashboard

Overall score: **0%****1** -

□ Question 72 of 94

A 28 year old woman who is 20 weeks pregnant is referred to you by her GP. She has a 2 month history of arthralgia, myalgia, and fatigue. She had initially put this down to pregnancy but was finding it increasingly difficult to do her job as a health care assistant in a local nursing home. She denied any shortness of breath, swallowing difficulties or alopecia.

She had asthma since childhood but was relatively well controlled on inhaled salbutamol as required and beclomethasone 400 micrograms twice daily.

She was a smoker of 10 cigarettes per day and had not drunk any alcohol since learning she was pregnant. She lives with her husband and 2 year old son. Her mother has a history of rheumatoid arthritis.

Her observations show a blood pressure of 138/86 mmHg and a heart rate of 92 beats per minute. Urinalysis showed a trace of protein.

On examination there was tenderness of the 2nd and 3rd metacarpalphalangeal (MCP) joints bilaterally and both wrists but no evidence of active synovitis. There are several painless mouth ulcers. You notice a few bruises on her arms but no other evidence of a rash. Her chest was clear and heart sounds were normal. Neurological examination was normal including full visual fields and eye movements.

Her bloods showed the following:

Haemoglobin	108 g/L
White Cell Count	$9.2 \times 10^9/\text{L}$
Platelets	$103 \times 10^9/\text{L}$
Neutrophils	$6.02 \times 10^9/\text{L}$
Lymphocytes	$0.80 \times 10^9/\text{L}$
Eosinophils	$0.90 \times 10^9/\text{L}$
ESR	29 mm/h

--	--

Urea	6.9 mmol/L
Creatinine	118 micromol/L
CRP	11 mg/L
Alkaline Phosphatase	87 iu/L
ALT	42 iu/L
Albumin	32 g/L

ANA	1: 320
dsDNA	24
Anti -Ro	Positive
Anti -La	Positive
Rheumatoid Factor	Positive
Anti CCP	Negative
Antiphospholipid antibody	negative

Given the most likely diagnosis, what complication needs to be discussed with her?

	Post partum haemorrhage
	Congenital heart block
	Deep vein thrombosis
	Pre-eclampsia
	Scleritis

A 76-year-old is investigated for persistent and progressive pain in his back and left hip. This is no longer responding to standard analgesia and has resulted in him taking regular modified-release morphine sulphate. Standard plain films of his left hip did not show changes consistent with osteoarthritis.

An isotope bone scan is therefore ordered to investigate his pain further:

What is the most likely cause of his pain?

	Multiple myeloma
	Metastatic prostate cancer
	Paget's disease of the bone
	Osteoporosis
	Ankylosing spondylitis

□ Question 74 of 94

A 49 year old woman presents with a one year history of joint pain and an intermittent purpuric rash. For the last 3 month she feels more fatigued than usual with malaise, fever and intermittent abdominal pain. She had an appendectomy 10 years ago. Beside that there is no past medical history of significance.

On clinical examination the only abnormality is a purpuric rash involving her calves and thighs.

The results of initial investigations showed a normal full blood count, but impaired renal function with a plasma creatinine of 160 $\mu\text{mol/l}$.

Another set of investigations were ordered to reach a diagnosis:

Na ⁺	135 mmol/l
K ⁺	4 mmol/l
Creatinine	165 mmol/l
Urea	11 mmol/l
CRP	50 mg/l
ESR	70 mm/hr
Urine analysis	Protein +, RBCs ++
Rheumatoid factor	negative
C3 and C4 levels	normal
cANCA	positive
pANCA	positive
ANA	negative

Renal biopsy showed focal necrosis, crescent formation, and absence of immunoglobulin deposits on immunofluorescence.

What is the most likely diagnosis?

	Rheumatoid vasculitis
	Mixed cryoglobulinaemia
	Wegner's granulomatosis (WG)
	Microscopic polyangitis (MPA)
	Systemic lupus erythematosus (SLE)

□ Question 75 of 94

A 70 year old man with rheumatoid arthritis presents for his monthly monitoring bloods because he is on methotrexate. He takes methotrexate 20mg once a week with folic Acid 5mg once weekly on a different day. He currently feels well in himself and his arthritis is well controlled. He does not drink alcohol or smoke. His monitoring blood tests come back as follows:

Hb	140 g/l	Na ⁺	139 mmol/l	Bilirubin	14 µmol/l
Platelets	240 * 10 ⁹ /l	K ⁺	4.2 mmol/l	ALP	100 u/l
WBC	7 * 10 ⁹ /l	Urea	5 mmol/l	ALT	80 u/l
Neuts	4.5 * 10 ⁹ /l	Creatinine	87 µmol/l		

What is the correct course of action?

	Stop methotrexate
	Reduce methotrexate dose to 10mg once weekly
	Switch methotrexate to sulfasalazine
	Continue on current dose with repeat bloods in one month
	Stop methotrexate and urgent liver USS

□ Question 77 of 94

A 72-year-old man attends rheumatology clinic for review of his osteoporosis treatment after being referred by the orthopaedic team. The patient had been diagnosed with osteoporosis six years previously after a DEXA scan had been arranged by his General Practitioner. Treatment with alendronic acid (70 mg weekly) had been initiated immediately after the diagnosis. After five years of bisphosphonate treatment, a repeat DEXA scan had been arranged and following review in rheumatology clinic, a treatment break had been agreed with the patient. Unfortunately, one year after stopping alendronic acid, the patient had tripped and fractured his right neck of femur, subsequently undergoing hemiarthroplasty.

Other past-medical history was significant for an episode of giant cell arteritis 10 years previously that had necessitated a prolonged course of corticosteroids. However, patient was now successfully weaned from corticosteroid treatment and remained in remission. The patient had never been diagnosed with rheumatoid arthritis and did not smoke cigarettes or drink alcohol. There was no family history of fragility fractures that the patient could recall.

On questioning, the patient reported that he had never had any adverse effects from alendronic acid treatment and would be happy to take this medication again if recommended.

Height	185 cm
Weight	90 kg
Femoral neck BMD (6 years previously)	T - 2.7
Femoral neck BMD (1 year previously)	T - 2.3

What is the most appropriate next step in the management of the patient's osteoporosis?

	Repeat DEXA scan not required, start treatment with zoledronic acid
	Repeat DEXA scan not required, restart treatment with alendronic acid
	Repeat DEXA scan in one year
	Repeat DEXA scan not required, start treatment with denosumab
	Repeat DEXA scan immediately

□ Question 78 of 94

□ □

An 85-year-old woman presents with a long history of poorly controlled type 2 diabetes mellitus presents to her GP complaining of a swollen right foot. She describes it as a 'gammy' foot and says she is always tripping over it. The pain is described as being 2 out of 10. The patient also describes reduced sensation up to her ankles.

On examination she has reduced sensation in both feet. The right midfoot is swollen, warm and slightly erythematous but there is no ulcer present. The dorsalis pedis pulse is difficult to feel on the right hand side.

An x-ray is requested:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Septic arthritis of the 1st metatarsophalangeal joint
	Osteomyelitis
	Charcot joint

	Critical ischaemia of the right foot secondary to peripheral arterial disease
	Gout

□ Question 80 of 94

A 46-year-old gentleman was referred by his GP to the respiratory clinic with deteriorating asthma control. He was diagnosed by his GP 2 years ago following complaints of feeling short of breath on exertion with wheeziness. Unfortunately, his symptoms deteriorated despite a trial of Clenil modulate 1000mcg BD, salmeterol 200mcg BD and montelukast 10mg OD. Upon further questioning, he stated that he had pins and needles in both hands as well as numbness of his fingertips for the last few weeks. His past medical history included hypertension, gout and sinusitis for which he was prescribed ramipril 5mg OD, allopurinol 100mg OD, salbutamol PRN and mometasone nasal spray 50mcg BD. He smoked 20 cigarettes per day and consumed 12 units of alcohol per week.

On examination, he appeared unwell. His heart rate was 98 bpm, respiratory rate 18/min, oxygen saturations 94% on air and blood pressure 146/82 mmHg. His heart sounds were normal with a normal JVP and examination of the chest revealed bilateral expiratory wheezes globally. Examination of the abdomen was normal. Examination of the peripheral nervous system demonstrated a peripheral neuropathy with a glove and stocking sensory loss of the upper limbs. Examination of the skin revealed the presence of purpura on his lower legs.

Initial investigations revealed the following results:

Hb	102 g/l
Platelets	342 * 10 ⁹ /l
WBC	12.1 * 10 ⁹ /l
	Neutrophils 82% count Lymphocytes 7% count Eosinophils 10% count Monocytes 1% count
ESR	42 mm/hr

Na ⁺	141 mmol/l
K ⁺	3.9 mmol/l
Urea	6.2 mmol/l
Creatinine	78 µmol/l

Chest x-ray: bilateral scattered pulmonary shadowing in lower zones
ECG: heart rate 97bpm, normal sinus rhythm, QRS interval 112ms, QTc interval 424ms

Which of the following tests is most likely to lead to the underlying diagnosis?

	Anti glomerular basement membrane antibodies
	p-ANCA antibodies
	ANA antibodies
	Anti Jo-1 antibodies
	c-ANCA antibodies

Dashboard

Overall score: 0%

□ Question 81 of 94

A 40-year-old man presents to the Emergency Department with pain in his left foot. He thinks this may have been triggered by dropping a heavy box on it at work a few days ago. He is known to have type 2 diabetes mellitus which is managed with metformin. On examination there is erythema, tenderness and swelling in the distal, medial aspect of the left foot.

Bloods show the following:

Hb	145 g/l
Platelets	$311 \times 10^9/l$
WBC	$6.3 \times 10^9/l$
CRP	56 mg/l

An x-ray is requested:

© Image used on license from Radiopaedia

What is the most appropriate management?

	Naproxen
	Allopurinol
	Below-the-knee plaster cast
	Intravenous antibiotics
	Supportive stocking e.g. TubiGrip

□ Question 82 of 94

A 52-year-old female has presented to your neurology clinic reporting difficulty in lifting her arms during exercises at the gym over the past two months. She is distressed by her symptoms and is tearful, mentioning that she is also using significant amounts of make-up to cover a new purple rash and swelling around her eyelids. She reports no past medical history no recent trauma and is normally fit and well. She has had a dry cough for the past 5 months that she puts down to her previous social smoking when she would smoke up to 2 cigarettes whilst going out with friends every 2 weeks.

On examination, you note a limited range of passive movement in both shoulders and hips secondary to tender deltoids and hip flexors. Examination of power demonstrates 4- out of 5 symmetrically in hip flexion and shoulder abduction. An elliptical erythematous rash is present around her eyes, the skin around her fingers appear tough bilaterally. Auscultation of her chest reveals bibasal fine inspiratory crackles and normal heart sounds. Observations show she is currently has a low-grade temperature of 37.7 degrees. A chest radiograph demonstrates bilateral fibrotic changes.

Her admission blood tests are as follows:

Hb	121 g/l
Platelets	$590 \times 10^9/l$
WBC	$12.3 \times 10^9/l$
ESR	20 mm/hr
Creatine kinase	3000 u/l
LDH	250 u/l

What is the most likely unifying diagnosis?

	Inclusion body myositis
	Systemic sclerosis
	Dermatomyositis

	Polymyalgia rheumatica
	Fibromyalgia

□ Question 83 of 94

A 45 year old patient comes in with a polyarthralgia. She is getting cyclical fevers along with the pain and also mentions she gets a salmon pink rash on her torso. She says she has had flares of this in the past and previously has been admitted to ITU for intravenous medications but she cannot recall their names. Her flares started in her late twenties. She has not had a flare for many years now. Her regular medications consist of paracetamol 1g PRN and naproxen 500mg PRN. On examination she is tender in most of her joints including her hips, knees, wrists, shoulders and the small joints of her hands. Her observations show heart rate of 110/min, respiratory rate of 24/min, blood pressure of 96/65mmHg, oxygen saturations of 98% on room air and temperature 39°C. Her blood tests reveal:

Hb	135 g/l	Na ⁺	136 mmol/l
Platelets	269 * 10 ⁹ /l	K ⁺	4.6 mmol/l
WBC	8 * 10 ⁹ /l	Urea	5 mmol/l
Neuts	6 * 10 ⁹ /l	Creatinine	90 µmol/l
Lymphs	2 * 10 ⁹ /l	CRP	55 mg/l
Eosin	0.1 * 10 ⁹ /l	Ferritin	1559 ng/ml

What is her diagnosis?

	Adult-onset Still's disease
	Rheumatoid arthritis
	Septic arthritis
	Psoriatic arthritis
	Tuberculosis

□ Question 84 of 94

An 80-year-old retired GP with no past medical history presents to hospital with a 6 month history of muscle aches and weakness. She also has difficulty swallowing and has had 3 courses of antibiotics for a presumed chest infection in the last 3 months. In the last 2 days she has been struggling to cope at home and has had two falls.

Blood tests show :

Erythrocyte Sedimentation Rate (ESR) 60 mm/hour g/l

Creatinine Kinase 8000 U/L

Which of the following blood tests would be LEAST helpful in the work up?

	Autoimmune profile
	FBC
	AST and ALT
	Urine myoglobin
	Renal biopsy

□ Question 85 of 94

A 72-year-old woman attends rheumatology clinic for review of her osteoporosis treatment. She had been diagnosed with osteoporosis five years previously on the basis of a DEXA scan (see results below). At that time, the DEXA scan had been arranged by her GP due to a strong family history of osteoporosis (maternal hip fracture) and the patient having received multiple courses of corticosteroids as treatment for asthma. The patient has never sustained a fracture of her hip, wrist or vertebrae. Following the initial diagnosis, the patient had been treated with alendronic acid 70 mg weekly. She had not experienced any adverse effects from this medication although reported finding the need to drink copious water with her dose onerous.

The patient's past medical history was significant for asthma, although the patient reported that this was now much better controlled than previously and she had not required any corticosteroid treatment in several years. She denied any history of thyroid disease or rheumatoid arthritis. The patient had never smoked and very rarely consumed any alcohol.

Details from the patient examination in clinic and selected results from her DEXA scans are given below.

Height	160 cm
Weight	65 kg
Femoral neck BMD (5 years previously)	T -2.6 g / cm ²
Femoral neck BMD (present day)	T -1.9 g / cm ²
FRAX 10-year probability of major osteoporotic fracture	18 %
FRAX 10-year probability of hip fracture	6.8 %

What is the most appropriate management of the patient's osteoporosis?

	Discontinue alendronic acid and initiate treatment with denosumab
	Hold further osteoporosis treatment with repeat DEXA scan in two years
	Continue treatment with alendronic acid with repeat DEXA scan in five years

	Continue treatment with alendronic acid with repeat DEXA scan in two years
	Hold further osteoporosis treatment with repeat DEXA scan in five years

□ Question 88 of 94

A 40 year old woman was diagnosed with fibromyalgia 6 months previously following review in Rheumatology outpatient clinic. She was subsequently discharged from clinic with a recommendation for trial of pregabalin therapy. The patient has now returned to her General Practitioner to report on-going symptoms of severe widespread body pain, severe fatigue and difficulty in concentrating on daily activities. The patient did not feel that starting pregabalin 6 months previously had offered any improvement in her symptoms. In fact, her symptoms had been causing more problems and she had recently been unable to attend her work as a teaching assistant.

The patients past medical history included a duodenal ulcer five years previously, induced by the combination of non-steroidal anti-inflammatory drug use and alcohol consumption. She also had a previous diagnosis of irritable bowel disease and had a tendency to become severely constipated. There were no known allergies to medications. The patient lived alone and in addition to her teaching assistant job was her elderly mothers primary carer.

On assessment by her General Practitioner, there was no evidence of inflammatory arthritis but multiple tender spots were demonstrated across the patients body. The patient was clearly distressed and frustrated with her on-going symptoms and had concerns for her ability to continue in paid employment. The patients affect was otherwise unremarkable with a good rapport maintained throughout. She denied any symptoms of low mood or thoughts of self-harm.

Following further discussion, the patient was keen to try a further pharmacological therapy as treatment for her fibromyalgia symptoms. She was reluctant to engage with suggested psychological therapies.

What is appropriate next line pharmacological treatment for the patients fibromyalgia?

	Continue pregabalin, start duloxetine
	Continue pregabalin, start ibuprofen as required
	Stop pregabalin, start duloxetine
	Stop pregabalin, start amitriptyline
	Continue pregabalin, start fluoxetine

Dashboard

□ Question 89 of 94

A 29 year old woman is referred to Rheumatology clinic after experiencing all over pain throughout her body over the past two years. This has been associated with not feeling refreshed in the morning after a nights sleep and the patient finding difficulty in concentrating on her work in a call centre. She denied any history of skin rashes, photosensitivity, hair loss, swallowing difficulties or dry eyes and she had not lost any weight. Past medical history was significant for a previous diagnosis of mild depression treated with a course of cognitive behavioural therapy. There was no family history of connective tissue disease. The patient lived with her husband and two young children and reported some on-going concerns over the family finances. She smoked 10 cigarettes per day but rarely drank alcohol.

Initial review of the patient had demonstrated no evidence of inflammatory arthritis but showed the patient had significant muscular tenderness at multiple sites throughout the body.

Initial blood tests requested after clinic review had been unremarkable and included negative rheumatoid factor and negative anti-nuclear antibody. X-rays of the patients hands and feet did not demonstrate any evidence of erosive arthropathy.

At a follow-up review of the patient with the above results it was discussed that no evidence of inflammatory arthritis had been uncovered and that the patients symptoms were most likely consistent with fibromyalgia. Given her previous experience with cognitive behavioural therapy the patient was keen to adopt positive lifestyle strategies to reduce her symptoms rather than pharmacological treatment.

Which non-pharmacological treatment below has most evidence of effectiveness in fibromyalgia?

	Strength training
	Balneotherapy
	Aerobic exercise
	Electrotherapy
	Acupuncture

Overall score: **0%**

□ Question 92 of 94

□ □

A 72 year old presents by blue light ambulance to A&E. He has been increasingly drowsy over the past 4 days and has not been out of bed for the past 48 hours. His wife reports two episodes of sweating and a high temperature during this period. He has been admitted three times in the last 9 months with urinary tract infections and is awaiting a transurethral resection of his prostate for benign prostatic hypertrophy. His other past medical history includes type 2 diabetes mellitus, diagnosed 4 years ago, and rheumatoid arthritis, diagnosed 16 years ago. His wife tells you that he appears to be prone to infections over the past few years. He normally walks with a stick but his exercise tolerance has been decreasing since doctors told him that he had 'scarring of his lungs from his rheumatoid.' On examination, he is sleepy but easily rousable and orientated to time and place. He is cool peripherally, with dry mucous membranes and JVP +1cm above the angle of Louis. Blood pressure measures 82/55mmHg, heart rate is 105/minute. You note conjunctival pallor, bilateral ulnar deviation of his hands, an inflamed second MTP joint and nodules beneath both elbows. Auscultation of the chest demonstrates bibasal inspiratory fine crackles. Abdominal examination demonstrates a 2cm liver edge and a 13cm spleen. Neurological examination is unremarkable. Routine blood tests and blood cultures are taken. What is the most appropriate treatment?

	Oral antibiotics as per local guidelines for mild-moderate community acquired pneumonia
	Intravenous antibiotics as per local guidelines for severe community acquired pneumonia
	Intravenous antibiotics as per local guidelines for urosepsis
	Intravenous antibiotics as per local guidelines for intra-abdominal sepsis
	Intravenous antibiotic as per local guidelines for neutropenic sepsis

Blood pressure measures 82/55mmHg, heart rate is 105/minute. You note conjunctival pallor, bilateral ulnar deviation of his hands, an inflamed second MTP joint and nodules beneath both elbows. Auscultation of the chest demonstrates bibasal inspiratory fine crackles. Abdominal examination demonstrates a 2cm liver edge and a 13cm spleen. Neurological examination is unremarkable. Routine blood tests and blood cultures are taken. What is the most appropriate treatment?

	Oral antibiotics as per local guidelines for mild-moderate community acquired pneumonia
	Intravenous antibiotics as per local guidelines for severe community acquired pneumonia
	Intravenous antibiotics as per local guidelines for urosepsis
	Intravenous antibiotics as per local guidelines for intra-abdominal sepsis
	Intravenous antibiotic as per local guidelines for neutropenic sepsis

□ Question 93 of 94

A 74-year-old woman attends rheumatology clinic for a review of her osteoporosis treatment. The patient had been diagnosed with osteoporosis on a DEXA scan five years previously after she fell and sustained a Colles fracture on the left side. Following this diagnosis, the patient had been initiated on treatment with alendronic acid.

In clinic, the patient reported that she had recently been suffering from nagging back pain over the past few weeks. She denied any history of recent falls or other trauma.

Past medical history was significant for rheumatoid arthritis, diagnosed when the patient was 28 years old. Following this diagnosis, she had received prolonged treatment with corticosteroids in association with a variety of disease modifying drugs. Ultimately, good control of her arthritis had been achieved using methotrexate (10 mg weekly) and the patient had not required corticosteroid treatment for many years. The patient reported no family history of osteoporosis or fragility fractures. She did not smoke or drink any alcohol.

The patient reported no concerns or side effects associated with taking her weekly alendronic acid (70 mg weekly).

Examination of the patients spine demonstrated mid-line point tenderness around the T12 - L1 level. Neurological examination of the lower limbs was unremarkable.

Thoracolumbar spine x-ray: anterior height loss of T12 vertebrae, otherwise unremarkable

Height	150 cm
Weight	55 kg
Femoral neck BMD (5 years previously)	T - 3.2
Femoral neck BMD (present day)	T - 2.4
FRAX 10-year probability of major osteoporotic fracture	27 %
FRAX 10-year probability of hip fracture	8.7 %

What is the most appropriate management of the patient's osteoporosis?

Hold further osteoporosis treatment with repeat DEXA scan in two years

	Hold further osteoporosis treatment with repeat DEXA scan in five years
	Discontinue alendronic acid and initiate treatment with denosumab
	Discontinue alendronic acid and initiate treatment with zoledronic acid
	Continue treatment with alendronic acid with repeat DEXA scan in five years

□ Question 94 of 94

A 54-year-old man is referred to rheumatology with a 6 month history of pain and stiffness in his fingers. He had also been feeling generally tired for the past few weeks. His GP has performed blood tests which show the following:

Hb	13.1 g/l
Platelets	$411 \times 10^9/l$
WBC	$4.5 \times 10^9/l$
CRP	35 mg/l
Rheumatoid factor	Negative

An x-ray of his hands is shown below:

□ Question 1 of 156

A 46-year-old male was transferred to the Intensive Care Unit (ICU) as an emergency admission. He had been scheduled to undergo an elective open cholecystectomy under general anaesthetic. He had been intubated and ventilated successfully, but a few minutes into the operation he had become tachycardic, with his heart rate rising from a resting rate of 72 bpm to a rate of 142bpm. His oxygen saturations dropped down to 92% on 15 litres of oxygen per minute, and his blood pressure rose from his baseline of 114/78 mmHg up to 162/98 mmHg. In addition, his end tidal CO₂ concentration rose, despite several checks to ensure that the tracheal tube was correctly sited. His past medical history was unremarkable except for an appendicectomy under general anaesthetic aged 26 yrs old.

The operation was abandoned. Upon his arrival to ICU, he was intubated and ventilated, maintaining an oxygen saturation of 96% on 15 litres per minute of oxygen. He appeared flushed and had significant muscle rigidity. His blood pressure had risen to 174/102 mmHg, and his heart rate was 136bpm. His temperature was 38.2 C. Examination of the cardiovascular revealed vasodilated peripheries with a bounding pulse and normal heart sounds. Auscultation of the lungs revealed good air entry in all zones and a correctly cited tracheal tube. Examination of the abdomen was unremarkable. Examination of the neurological system confirmed the presence of equal and reactive pupils, with generalised muscle hypertonicity and masseter muscle spasm. A central venous catheter and arterial line were inserted. The central venous pressure was 9 cm.

An arterial blood gas sample on 15 litres of oxygen was taken:

pH	7.26
HCO ₃	18 mmol/l
PaO ₂	17 kPa
PaCO ₂	7.6 kPa
Na ⁺	139 mmol/l
K ⁺	7.1 mmol/l

What is the next best immediate management step?

	Commence IV labetalol infusion
--	--------------------------------

	Commence IV meropenem
	Commence high dose IV hydrocortisone
	Commence IV dantrolene
	Arrange immediate therapeutic hypothermia

Dashboard

Overall score: **0%**

Question 3 of 156

□ □

A 55-year-old lady presents to her general practitioner with a painful rash on her breasts. The rash has developed over the last 24 hours and although initially diffuse and red is now well demarcated and a much darker red. She was started on warfarin five days ago for a deep vein thrombosis diagnosed on ultrasound doppler. She has a past medical history of hypothyroidism, type two diabetes mellitus, thromboembolism and obesity. She remembers having been on warfarin at least once before for previous deep vein thrombosis but does not remember ever having had this rash. Her blood tests today are as follows.

Prothrombin time	21.4 seconds
INR	2.1 ratio

What is the most likely diagnosis?

	Protein S deficiency
	Idiosyncratic drug reaction
	Stevens Johnson syndrome
	Warfarin toxicity
	Protein C deficiency

Dashboard

□ Question 4 of 156

A 19-year-old woman is referred to the acute medical team after presenting to the emergency department. The patient reports taking an overdose of paracetamol that evening, following an argument with her mother. She immediately regretted taking the overdose and asked her mother to take her to the hospital. She is now very upset and anxious that she has caused herself serious harm and is requesting treatment.

The patient took just under two packets of 500 mg paracetamol tablets (an estimated 28 tablets), 40 minutes prior to presentation to hospital. She denied any history of mental or physical health problems, and had never taken an overdose before. She took no regular medications and did not drink alcohol.

Examination revealed an alert but anxious young woman with observations within normal physiological parameters, and no abnormal physical signs.

Haemoglobin	128 g / dL
Mean cell volume	95.0 fl
White cell count	8.4×10^9 / microlitre
Platelets	198×10^9 / microlitre
Urea	4.3 mmol / L
Creatinine	67 micromol / L
Sodium	137 mmol / L
Potassium	4.3 mmol / L
Albumin	45 g / L (reference 35-50)
Alkaline phosphatase	56 U / L (reference 35-100)
ALT	34 U / L (reference 3-36)
Bilirubin	15 micromol / L (reference < 26)
International normalised ratio	1.1 (reference 0.8-1.2)

What is the most appropriate management of the patient's paracetamol overdose?

	Treatment with activated charcoal if 4-hour paracetamol level > 100 mg / L
	Immediate treatment with acetylcysteine
	Haemodialysis
	Immediate treatment with methionine
	Immediate treatment with activated charcoal

Dashboard

Overall score: 0%

Question 5 of 156

A 47 year old Latvian man is brought to the Emergency Department by two of his friends. He is confused and aggressive and walks with an unsteady gait. History is difficult to obtain from the patient due to slurring of his speech and a slight language barrier. You note that he fails to meet your gaze when you are talking to him. Examination shows a GCS of 15/15 but he is drowsy and irritable. There is a vague smell of alcohol on his breath. He is flushed in the face and his eyes are red and hyperaemic. Pupils are slow to react to direct light but equal in size. Cardiorespiratory examination is unremarkable aside from a respiratory rate of only 8/min but SpO₂ is 98% on air. Abdomen is soft and non tender with no hepatomegaly and no signs of chronic liver disease. Despite the department being well lit he asks you to turn the lights on.

Biochemistry reveals:

Haemoglobin	149g/L	Sodium	150mmol/L	pH	7.25
White cells	8.9x10 ⁹ /L	Potassium	5.9mmol/L	pCO ₂	3.9kPa
Neutrophils	5.9x10 ⁹ /L	Urea	13.8mmol/L	pO ₂	12.6kPa (air)
Platelets	229x10 ⁹ /L	Creatinine	156mol/L	HCO ₃ ⁻	12.5mmol/L
Prothrombin time	11 sec	Glucose	24.7mmol/L	BE	-13.2mEq/L
Ethanol	110mg/dL	Chloride	100mmol/L	Lactate	2.0mmol/L
Anion gap	38	Osmolar gap	25 (-10 to +15)		

What is the most appropriate next step in the management of this patient?

	Begin high dose oral folic acid and vitamin B complex
	Establish IV access and begin fast fluids with Pabrinex I+II (Vitamin B12)
	Establish IV access and send blood for methanol levels; give oral ethanol in the form of neat 40% whiskey at a dose of 175ml
	Establish IV access and send blood for methanol levels; begin IV fomepizole 1000mg in 500ml 5% dextrose

	over 30 minutes
	Refer to Intensive Care to begin haemofiltration

Dashboard

□ Question 6 of 156

□ □

A 42 year old computer programmer is brought to the Emergency Department by his wife with chest pains. He is haemodynamically stable with a blood pressure of 105/69mmHg and a heart rate of 92bpm but he is peripherally shut down with cool, dusky extremities and weak peripheral pulses. He complains of crushing central and left sided chest pain with some evidence of sweating and pallor. He also complains of severe global headache. His chest is clear and his heart sounds are normal. Chest x-ray is unremarkable.

An ECG shows pronounced inferior and lateral ST segment depression. A baseline troponin at 4 hours since onset of chest pain is raised. His wife tells you he has been taking clarithromycin from the GP for the past 6 days for a chest infection and she has been concerned he has been acting strangely since starting this with confusion, excitability, delusions and visual hallucinations. He has also had stomach cramps and diarrhoea for the past 2 days. His medical history is significant for migraines for which he takes PRN zolmitriptan and prophylactic ergotamine.

Which one of the following explains this patients symptoms most completely?

	Acute non-ST segment myocardial infarction
	Acute meningoencephalitis
	Clarithromycin induced haemolytic uraemic syndrome (HUS)
	Ergotism
	Serotonin syndrome

Question 7 of 156

A 20-year-old female admits to abusing codeine and diclofenac, up to 30 tablets per day. She attends the emergency department demanding help with her addiction. Her baseline bloods include:

pH	7.28
PCO2	2.9 kPa
PO2	8.5 kPa
HCO3- 16 mmol/l	

Na+	130 mmol/l
K+	6 mmol/l
Cl-	110 mmol/l
HCO3-	16 mmol/l

What is the most likely diagnosis?

	Lactic acidosis
	Type 1 renal tubular acidosis
	Type 2 renal tubular acidosis
	Type 4 renal tubular acidosis
	Ketoacidosis

Question 9 of 156

□ □

A 20-year-old man is brought to the Emergency Department by the Police with agitation and aggression. He is accompanied by a friend, who says they had been out celebrating his brother's birthday and that the patient may have 'snorted something'.

He recalls the patient complaining of intense nasal pain for some time after he allegedly took the substance, but it soon settled and he seemed in good spirits; talking enthusiastically about seeing vivid lights and waves emanating from the club's speakers. As the night went on, however, he became increasingly disturbed; shouting at other clubgoers and complaining about hearing threatening voices.

On examination, his temperature is 39.2°C. His pulse is 117bpm and his blood pressure is 181/98mmHg. He is difficult to examine due to intermittent aggression, and he has lashed out on several occasions.

In order to ensure his own safety, a decision to sedate the patient is made. The patient is successfully restrained and cannulated but suffers a tonic-clonic seizure shortly afterward. He is given 4mg IV lorazepam, but then suffers a cardiac arrest from which he cannot be resuscitated.

Which drug is most likely to be responsible?

	Lysergic acid diethylamide (LSD)
	Nexus (2CB)
	Spice
	Gamma-hydroxybutyric acid (GHB)
	Methoxetamine

Dashboard

Question 11 of 156

A 20-year-old female presents having taken 20 aspirin 500mg tablets in a suicide attempt. She has felt well since and is asymptomatic, and now regrets these actions. She has a background of borderline personality disorder for which she takes olanzapine and has never attempted suicide in the past. She was seen by her GP with a presumed respiratory tract infection one week ago and prescribed amoxicillin. Cardiovascular, respiratory and abdominal examinations are all unremarkable. Her blood gas reveals a ph 7.41, lactate 0.5mmol/L and laboratory bloods are unremarkable other than a salicylate level 4 hours post ingestion of 660mg/L.

Which management step should be taken next?

	Intravenous (IV) Sodium Chloride 0.9%
	Reassure and discharge
	IV Sodium bicarbonate 1.26%
	N-acetylcysteine infusion
	Dialysis

Dashboard

Question 12 of 156

You are the on-call medical doctor called to review a patient in the Emergency Department. A 54 year old male patient with a past history asthma, ischaemic heart disease and transient ischaemic attack has presented with palpitations. His admission ECG shows a regular, narrow complex tachycardia. Vagal manoeuvres have been tried in the department with no success. You decide to give intravenous adenosine in an attempt to chemically cardiovert. An initial dose of 6mg is given into a proximal vein with a large flush. The patient soon loses consciousness and an 11 second ventricular standstill is noted on the rhythm strip before slow return of sinus rhythm.

Which of the patient's medications is most likely to be responsible for this?

	Phyllocontin
	Dipyridamole
	Bisoprolol
	Simvastatin
	Montelukast

Question 14 of 156

□ □

A 56-year-old man is brought into hospital with palpitations, restlessness and agitation. His wife tells you he has lost 2 kilograms of weight over the past month. She attributes this to persistent diarrhoea over the same period.

He has a past medical history of persistent atrial fibrillation and takes amiodarone.

On examination, he has a heart rate of 144 beats per minute and his ECG confirms atrial fibrillation with no ischaemic changes. You are unable to palpate any abnormality of the thyroid cartilage.

Investigations are as follows:

TSH	0.1 mU/L
⁹⁹ Tc scan	reduced uptake

Which of the following is the most important step in this patient's immediate management?

	Carbimazole
	Corticosteroids
	Propylthiouracil
	Thyroidectomy
	Increase dose of amiodarone

□ Question 16 of 156

A 75-year-old man is an inpatient on the orthopaedic ward recovering from an elective knee replacement performed three days previously. The patient's immediate post-operative recovery had been unremarkable and he had begun to mobilise with the ward physiotherapist. Routine observations recorded on the ward had been unremarkable during the previous 24 hours.

During her drug round, the patient's nurse saw the patient suddenly become unable to breathe and clutch at his chest. After calling for help the nurse went to her patient and found him to be in cardiac arrest. Resuscitations attempts were initiated following advanced life-support protocol. Please see the below table for a summary of the patient's electrical rhythm and treatments administered during the initial phases of the resuscitation attempt.

The patient was noted to be in good physical health with his only comorbidity being hypertension, well controlled with medication. The patient's admission clerking recorded that he was a retired schoolteacher who lived independently at home with his wife. A review of the patient's drug chart indicated that he had been receiving subcutaneous enoxaparin as prophylaxis against venous thromboembolism, but that the patient had refused to wear compression stockings during his admission as he found them uncomfortable.

Number of rhythm check	Result of rhythm check	Treatment administered
1	Pulseless electrical activity	IV adrenaline 1 mg
2	Ventricular fibrillation (coarse)	DC shock 150 J
3	Ventricular fibrillation	???

In addition to a further DC shock, what is the appropriate choice of IV drug treatment following the third rhythm check?

	IV adrenaline 1 mg
	IV atropine 400 micrograms & IV amiodarone 300 mg
	No IV drug treatment indicated

	IV adrenaline 1 mg & IV amiodarone 300 mg

□ Question 21 of 156

A 45-year-old man was found unconscious at home by his partner, with empty packs of flecainide, codeine and valerian root tablets besides him. He was only found after his partner got worried when he had locked himself in his room and after 4 hours not heard any sounds from the room. He had been depressed for the past couple of months and relations between him and his partner had been strained. He has a past medical history of back pain, paroxysmal atrial fibrillation, angina and hypertension.

On examination, he was drowsy, unable to give a history, with a heart rate of 50bpm, respiratory rate of 16 breaths per minute, oxygen saturation of 96% on air, and a blood pressure of 110/58mmHg. Pupils were 3mm and equal and reactive to light.

Investigations:

Na ⁺	136 mmol/l
K ⁺	4.6 mmol/l
Urea	10.9 mmol/l
Creatinine	110 µmol/l
Serum bilirubin	30 µmol/l
Serum alkaline phosphatase	135 IU/l
Serum aspartate aminotransferase	50 IU/l
C Reactive protein	2mg/l
Haemoglobin	14.6 g/dl
White cell count	5.6 x 10 ⁹ /L
INR	1.4

ABG (on air):

pH	7.258
----	-------

pO2	11.7 kPa
pCO2	3.4 kPa
Lactate	1.6 mmol/l
Base Excess	-8.4 mmol/l
Bicarbonate	11.9 mmol/l

ECG showed bradycardia with widened QRS complexes and giant inverted T waves.

After fluid resuscitation, what is the next single most important management step?

	Activated Charcoal
	Magnesium Sulphate
	Sodium Bicarbonate
	Haemodialysis
	N-Acetyl Cysteine infusion (NAC)

Question 23 of 156

□ □

A 60 year old man with a known history of congestive cardiac failure and asthma is reviewed in a cardiology clinic. He is noted to have a blood pressure of 95/63mmHg and a heart rate of 98bpm. An ECG confirms sinus rhythm. He has previously developed symptoms of wheeze with beta blockade. He is commenced on ivabradine 5mg twice daily by his cardiologist.

Which of the following should the patient be warned of as a recognised side effect of ivabradine?

	Neutrophilia
	Hypotension
	Phosphenes
	Diaphoresis
	Renal failure

Question 24 of 156

□ □

A 27-year-old female with known HIV patient presents on the medical take with rigours, worsening cough and shortness of breath. She was diagnosed with pulmonary tuberculosis following a recent inpatient stay and discharged 1 month ago.

Lab results from her previous admission show a CD4 count of 120 and a viral load of 100,000 copies/mL. She was initially started on TB therapy and commenced HAART shortly before discharge.

On examination she has a temperature of 38.5°C, a heart rate of 92 beats per minute, a blood pressure of 118/76 mmHg, and a respiratory rate of 22/min. Auscultation of the chest reveals coarse crackles in the right mid and upper zone, there is also a dullness to percussion and quiet breath sounds at the right base. There is no lymphadenopathy and the remainder of the clinical examination is normal. A repeat chest x-ray today shows a worsening of right sided parenchymal consolidation and a new right sided pleural effusion.

What is the most appropriate management?

	Sputum drug sensitivity testing
	Drain the effusion and send fluid to microbiology for drug sensitivity testing
	Admit to hospital and organise directly observed therapy for her TB
	Add amphotericin
	Add prednisolone 30mg PO OD

Question 26 of 156

□ □

A 80-year-old man with a past medical history of gout, reflux and ischaemic heart disease is admitted to the emergency department with a atrial fibrillation with fast ventricular response. He is managed according to ALS protocol and is stabilised.

A full set of bloods are sent and are displayed below:

Hb	135 g/l
Platelets	$260 \times 10^9/l$
WBC	$6 \times 10^9/l$

Mg	0.34 $\mu\text{mol/l}$
Ca (adj)	2.1 u/l
PO4	0.8 u/l

This is discussed with the cardiology registrar, who advises correction of the magnesium.

What medication is the most likely cause of hypomagnesaemia in this case?

	Aspirin
	Omeprazole
	Ranitidine
	Colchicine
	Ramipril

A 30-year-old woman with rheumatoid arthritis has been diagnosed in the community with a prolonged urinary tract infection. For her rheumatoid arthritis she has been stable on azathioprine for nearly a year and besides paracetamol she takes no other regular medications.

The GP has requested a follow-up blood test which is shown below.

Baseline bloods were taken 2 months ago:

Hb	120 g/l
Platelets	$310 \times 10^9/l$
WBC	$4.5 \times 10^9/l$

Yesterday the bloods showed the following:

Hb	101 g/l
Platelets	$296 \times 10^9/l$
WBC	$1.9 \times 10^9/l$

Which of the following drugs is most likely responsible?

	Trimethoprim
	Nitrofurantoin
	Cephalexin
	Amoxicillin
	Co-amoxiclav

☐ Question 29 of 156

A 19 year old man is brought into the Accident & Emergency department by his parents who are very concerned about his well being, and a medical opinion is sought. He arrived home from an evening with friends and was behaving bizzarely. When you talk to him, he tells you that he is feeling on top of the world and that he is an angel sent from god. He also describes seeing music as colours coming out of the radio earlier in the evening. He describes colours being more vivid and vibrant but denies any hallucinations. He has been unable to sleep for the past 24 hours

On examination, he is confused and disorientated but alert, skin colour is normal, central capillary refill time less than 2 seconds with moist mucous membranes. Normal eye movements, no peripheral focal neurology HR 115 sinus tachycardia (ECG normal) Blood tests (essentially normal) RR 16. Pupils dilated but responsive to light equally BP 174/98. When you are testing his eye movements he describes seeing trailing colours and when he closes his eyes he can see after-images that persist for a few seconds. He repeatedly asks you for glasses of water during the consultation and drinks them quite rapidly.

His mother says that he has no past history of medical problems and that his mental state has been normal until today and that he was well before he left the house 6 hours ago this evening. There is a family history of depression and he has recently left university due to not achieving the required grades

Towards the end of the consultation, he suddenly becomes very agitated and fearful, pointing at a wall believing that he is being chased by a monster, his family are unable to comfort him or lessen his agitation.

What is the the most appropriate treatment to give at this time?

	Haloperidol 5mg IM
	Lorazepam 1mg IM
	Lorazepam 1mg PO
	Olanzapine 10mg PO
	Lorazepam IV 1mg and cyproheptadine.

□ Question 34 of 156

A 45 year old man is admitted from a local park. On arrival he is in respiratory distress with a ventilatory rate of 34 breaths per minute and a peripheral oxygen saturation of 89% on 15L/min oxygen via non-rebreathe mask. He is grey and sweaty with central cyanosis. Heart rate is 122bpm and blood pressure is 94/66mmHg. Examination of the chest discloses a normal cardiorespiratory examination and there is no clinical indication of heart failure. A chest xray shows no acute pathological lesion but background emphysematous changes and an ECG shows only sinus tachycardia with a corrected QT interval approaching the upper limit of normal with no ischaemic lesions.

An arterial blood gas taken on 15L/min oxygen shows:

pH	7.17	HCO ₃ ⁻	13.4	Glucose 6.9 mmol/l	MetHb	35%
pO ₂	10.9	Base excess	-5.8	Potassium 5.5 mmol/l	COHb	8%
pCO ₂	6.7	Lactate	4.1 mmol/l			

He is beginning to show signs of tiring and confusion and his GCS has fallen to 13/15 (E3V4M6) but he tells you he has been inhaling Liquid Gold (an alkyl nitrite).

Which of the following interventions is most appropriate in this patients immediate management?

	Continuous positive airways pressure ventilation (CPAP) pending transfer to a hyperbaric chamber
	Reduce inspired oxygen concentration and controlled oxygen therapy via Venturi valve
	75mg 1% methylthioninium chloride solution IV over 5 minutes
	300mg 3% sodium nitrite solution IV over 10 minutes
	50ml 8.4% sodium bicarbonate solution IV over 20 minutes

Overall score: **0%**

A 67 year old type 2 diabetic visits you in endocrinology outpatients complaining of reduced mobility over the past 6 months. For the past 7 months, her blood glucose has been well controlled on the same regime of metformin and pioglitazone. In addition, she has a past medical history of two previous CABGs for ischaemic heart disease, hypertension and an active 35 pack year smoking history. She reports no orthopnoea or recent chest pain. On examination, her respiratory, cardiovascular and abdominal examinations are unremarkable. However, you note bilateral lower limb swelling to both knees, which she reports to have been of gradual onset over the past 6 months. You note no evidence of varicose veins or clinical signs of deep vein thrombosis. Urine dip is negative for glucose, leucocytes, nitrites and protein. A 12 lead ECG demonstrates normal sinus rhythm at 65/ minutes with normal voltage criteria. A recent echocardiogram 4 months ago demonstrate ejection fraction of 60% with no regional wall abnormalities. What is the most likely diagnosis?

	Silent myocardial infarctions
	Undiagnosed congestive cardiac failure resulting in fluid overload
	Diabetic nephropathy resulting in nephrotic syndrome
	Chronic venous insufficiency
	Pioglitazone resulting in fluid retention

A 20-year-old girl with multiple sclerosis (MS) attends the emergency department following a seizure. She was diagnosed with MS at age 16 and has received different immunomodulatory regimes in the past, including azathioprine. She commenced natalizumab 2 years ago. This is her first seizure however once recovered, she tells you that she has noticed she has been increasingly clumsy over the last 6 months, she drops things easily. In addition, she has had several episodes where her speech has been slurred and people have commented that she sounds tired. On examination, you find that her tone is normal throughout, power in all muscles groups in both upper and lower limbs is normal. On cranial nerve examination, you identify a right homonymous superior quadrantanopia however she does have a full range of eye movements and no ptosis. She has an ataxic gait. Her speech is normal throughout the history.

She is concerned, what is the diagnosis?

	Progressive multifocal leukoencephalopathy
	Transient ischaemic attacks
	Progression of multiple sclerosis
	Newly diagnosed epilepsy
	myasthenia gravis

Question 39 of 156

A 29 year old male Polish male presents to the Emergency Department with 48 hours of severe 'burning and sharp' electrical pains in his arms and legs. He is well known to the department, having been treated for alcohol withdrawal a number of times in the past and is a known intravenous drug user. He reports no weakness, dysarthria or hallucinations. He reports drinking about 7 pints of beer in the past 24 hours, which he says is normal for him, and has used intravenous heroin daily for the past 2 weeks.

On examination, both upper and lower limbs are rigid and mildly bradykinetic. A bilateral resting tremor is noted in both hands. Reflexes and sensation are normal. Examination of cranial nerves and eye movements are unremarkable.

His initial blood tests return and are as follows:

Hb	16.3 g/dl
Platelets	$276 \times 10^9/l$
WBC	$5.5 \times 10^9/l$
Vitamin B12	202 ng/l
Folate	471 (>317 nmol/l)

Na ⁺	142 mmol/l
K ⁺	4.3 mmol/l
Urea	6.4 mmol/l
Creatinine	85 μ mol/l
CRP	7mg/l
HIV	negative

Which investigation is most likely to yield the underlying diagnosis?

--	--

	DAT scan
	Anti-GM1b antibodies
	Borrelia burgdorferi serology
	Urine porphobilinogen
	Serum heavy metals

□ Question 40 of 156

A 45-year-old lady presents to the Emergency Department progressive shortness of breath for the last three days. It is worse on activity but is not associated with any cough or wheeze. She has a past medical history of asthma and HIV, for which takes antiretroviral medication regularly. At her last clinic appointment two weeks ago, she was found to have oral candida and so was given a 2 week course of nystatin and started on dapsone for prophylaxis of pneumocystis jirovecii pneumonia. She is a non-smoker.

On examination, her lips and nail beds have a bluish tinge and she is visibly breathless. Her respiratory rate is 26 per minute and on pulse oximetry her saturations are 91% on air both at rest and on exercise. Her temperature is 36.5°C and she has not felt feverish. On auscultation she has vesicular breath sounds with minimal wheeze and normal heart sounds with no murmurs. She has no ankle oedema and JVP is not raised. There is no evidence of oral candidiasis and no lymphadenopathy. Her calves are soft and non-tender.

A chest x-ray shows clear lung fields with no focal consolidation or lymphadenopathy. ECG is sinus rhythm at 90 beats per minute with normal complexes throughout.

Arterial blood gas on air:

pH	7.51
PaO ₂	13.7 kPa
PaCO ₂	3.34 kPa
HCO ₃ ⁻	22.1 mmol/l
BE	-3.3 mmol/l
sO ₂	97%
Hb	113 g/l
Na ⁺	143 mmol/l
K ⁺	3.7 mmol/l
Glu	5.2 mmol/l

Lac	1.9 mmol/l
-----	------------

What is the most likely diagnosis?

	Acute asthma
	Carbon monoxide poisoning
	Methemoglobinemia
	Pneumocystis jirovecii pneumonia
	Pulmonary embolus

□ Question 41 of 156

A 44-year-old man presents to the emergency department complaining of breathlessness. He reports that he was leaving a restaurant because he was starting to feel lightheaded, developed a headache and was breathless.

An ABG done on admission demonstrated carbon monoxide at 26%.

Three hours later he feels tired and weak, but his headache and lightheadedness have improved since admission. He has a past medical history of asthma which he reports to be well controlled, rarely needing his blue inhaler. He smokes 15-ciagarettes per day and has a 23 pack-year history. He works as a teacher in central London. On examination, he is receiving 15L of oxygen via a non-rebreather mask. His chest is clear on auscultation. Neurological examination is normal. An ECG demonstrates no ischaemic changes.

Observations:

Saturations	100%
Respiratory rate	16/min
Blood pressure	126/87mmHg
Heart rate	84/min
Temperature	36.8°C

What is the most appropriate management plan?

	Wean off oxygen guided by standard pulse oximetry saturation levels
	Prescribe IV mannitol
	Maintain high-flow oxygen until asymptomatic or carbon monoxide levels are <10%
	Refer urgently for hyperbaric oxygen treatment
	Arrange urgently for non-invasive ventilation

Question 42 of 156

□ □

A 22-year-old male is 'blue-lighted' to the Emergency Department having been found collapsed at a party. On arrival, his GCS is 3/15 and he is immediately intubated and ventilated by the Emergency Physicians.

On examination he is afebrile. He is mildly bradycardic at 53bpm and his blood pressure is 109/69mmHg. His pupils measure 2mm bilaterally. IV access is obtained and 400 micrograms of naloxone are administered without effect. The on-call radiologist is contacted and a CT head scan is arranged.

One hour later the patient extubates himself without warning. He is referred to medicine as his GCS is still 13/15. His CT demonstrates no acute intracranial pathology. By the time you arrive in the Emergency Department his GCS has improved to 15/15 and he is demanding to go home.

Which drug is most likely to be implicated?

	Diazepam
	Methoxetamine
	Gamma-hydroxybutyric acid (GHB)
	Heroin
	Methamphetamine

□ Question 45 of 156

A 28 year old woman was admitted to the Emergency Department drowsy and unwell after a suspected suicide attempt at home. The patient was under the care of the community psychiatry and had been receiving treatment for schizoaffective disorder. There was no other known past medical history. The paramedics bringing the patient to hospital also had brought the medications they found in the patient's home including Quetiapine, Levomepromazien, Zopiclone and Oxazepam. The paramedics reported that they had not seen evidence of empty medication packets or blister packs at the patient's home.

Initial assessment of the patient was unremarkable except for reduced consciousness level. Basic observations at presentation are listed below.

- Blood pressure: 150/79 mmHg
- Heart rate: 89 bpm
- Respiratory rate: 20 / min
- O2 saturations (15 L O2): 100 %
- Glasgow coma score: M5 V3 E2
- Blood glucose: 7.0 mmol / L
- Temperature: 36.8°C

Results from an arterial blood sample (15 L O2) were as follows.

pH	7.19
PaCO2	3.3 kPa
PaO2	21.2 kPa
Bicarbonate	8.9 mmol / L (reference 20.0-26.0)

Sodium	142 mmol / L
Potassium	3.6 mmol / L
Calcium	2.13 mmol / L (reference 2.20-2.60)
Chloride	110 mmol / L (reference 99-108)

Urea	5.2 mmol / L
Creatinine	110 micromol / L
Lactate	26 mmol / L
Plasma osmolality	380 mmol / Kg (reference 280-295)
Haemoglobin	12.0 g / dL

Based on the above blood results, what is the most likely cause of the patient's reduced consciousness level?

	Ethanol intoxication
	Benzodiazepene overdose
	Ethylene glycol intoxication
	Quetiapine overdose
	Chronic renal failure

Dashboard

Overall score: 0%

□ Question 47 of 156

A 70 year old man is admitted to hospital with chest pain associated with nausea and vomiting. There was no recent history of shortness of breath or wheeze. ECG demonstrated inferolateral ST depression and troponin was significantly elevated at 12 hours after symptom onset.

His past medical history included chronic obstructive pulmonary disease, hypertension and a previous MI 3 years previously. The patient reported two exacerbations of his COPD within the last 18 months, neither of which required hospital admission. He had never required intubation or non-invasive ventilation due to his COPD.

Regular medications included bendroflumethiazide 2.5 mg OD, inhaled tiotropium 18 microg OD and inhaled salbutamol 100 microg PRN. There were no known drug allergies. The patient was a retired engineer, an ex-smoker and lived independently with his wife.

The initial impression was of non-ST elevation myocardial infarction and treatment was initiated with aspirin, clopidogrel, fondaparinux, ramipril and atorvastatin. The patient subsequently mobilised pain-free on the ward and was discharged home with plan for outpatient stress echocardiogram.

Recent pulmonary function tests are given in the table below.

Forced vital capacity	105 % predicted
Forced expiratory volume (1s)	67 % predicted
FVC / FEV1	64 % predicted

Transthoracic echocardiogram: no valvular abnormality; mild-moderate systolic impairment of lateral left ventricle; normal right ventricular function

What is the most appropriate plan for beta-blockade therapy for this patient?

	Low dose bisoprolol with slow up-titration of dose

	Low dose carvedilol with slow up-titration of dose
	Low dose bisoprolol
	Low dose carvedilol
	Beta-blockade therapy inappropriate

Question 50 of 156

□ □

A 49-year-old woman comes to the Emergency department suffering from nausea and lethargy which has increased over the past few days. She has undergone a renal transplant for end stage renal failure due to chronic reflux nephropathy some 3 months ago. You understand her GP prescribed an antibiotic for a respiratory tract infection without checking for potential interactions with her ciclosporin based immunosuppressive regime. Creatinine has increased significantly, and ciclosporin is above the upper limit of the recommended range.

Investigations:

Na ⁺	142 mmol/l
K ⁺	5.1 mmol/l
Urea	8.2 mmol/l
Creatinine (3 months ago)	161 µmol/l
Creatinine (today)	225 µmol/l

Which of the following antibiotics is she most likely to have been prescribed?

	Amoxicillin
	Cephalexin
	Clarithromycin
	Doxycycline
	Levofloxacin

Overall score: **0%**

□ Question 51 of 156

A 28-year-old lady is brought in by her mother having taken an overdose of an unknown medication. She has recently broken up with her boyfriend and has been fired from her job for turning up late to work persistently. She was found in her room by her mother with a small bottle of vodka which was empty and some burnt medication packaging. She has no history of mental health disease, although did self-harm (arm cutting) twice whilst a teenager. She has no medical history other than being treated for malaria during a recent trip to west Africa. The patient is tearful, regrets the overdose and is currently complaining of nausea, epigastric discomfort, slightly blurred vision and a ringing in her ears.

On examination, her heart rate is 115 beats/min, her blood pressure 98/48 mmHg and she appears flushed. Her respiratory rate is 18 breaths per minute and her oxygen saturations 98% breathing room air. Her Glasgow coma score is 15/15 and her pupils are equal and reactive. Her blood results are as follows.

Na ⁺	135 mmol/l
K ⁺	4.3 mmol/l
Urea	5.1 mmol/l
Creatinine	86 µmol/l
Bilirubin	18 µmol/l
ALP	65 u/l
ALT	56 u/l

What is the most likely toxin?

	Quinine overdose
	Ibuprofen overdose
	Alcohol intoxication
	Paracetamol overdose

□ Question 52 of 156

A 24-year-old man with a history of depression and self-harm is brought to the emergency department by a friend 2 hours after an impulsive overdose of ferrous sulphate. He weighs 65kg and has ingested 65 x 200mg ferrous sulphate tablets. This is equivalent to 4225mg of elemental iron (65mg/kg).

On assessment, he denies any abdominal pain, diarrhoea or vomiting.

Observations are as follows:

- Temperature 36.5
- Respiratory rate 18/min
- Saturations 98% on air
- Heart rate 82bpm
- Blood pressure 136/74 mmHg

Venous blood results show:

Hb	133 g/l	Na ⁺	139 mmol/l	Bilirubin	8 µmol/l
Platelets	287 * 10 ⁹ /l	K ⁺	4.1 mmol/l	ALP	89 u/l
WBC	8.3 * 10 ⁹ /l	Urea	3.4 mmol/l	ALT	34 u/l
Neuts	4.2 * 10 ⁹ /l	Creatinine	72 µmol/l	Albumin	40 g/l
Lymphs	1.3 * 10 ⁹ /l			Serum iron	70 umol/l
Eosin	0.2 * 10 ⁹ /l			pH	7.40

Abdominal x-ray demonstrates the presence of iron in the stomach.

What is the appropriate initial medical management

	Whole bowel irrigation
	Activated charcoal

	Emergency endoscopy for removal of iron from the stomach
	Observe and repeat iron levels 4-6 hours after ingestion
	Administer desferrioxamine

Question 53 of 156

A 68-year-old lady is reviewed in the cardiology outpatient clinic following a recent admission for a non-ST-elevation myocardial infarction (NSTEMI). An echocardiogram performed during her inpatient stay showed mild-moderate LV systolic dysfunction with an ejection fraction of 40%.

Since discharge, she has been feeling well and has experienced no further episodes of chest pain. She reports only mild breathlessness on climbing two flights of stairs but draws your attention to an itchy rash on her lower legs. On examination, there are tense blisters covering her lower limbs bilaterally with minimal underlying oedema.

Which of her medications is most likely to be implicated?

	Spironolactone
	Clopidogrel
	Bisoprolol
	Furosemide
	Ramipril

Question 57 of 156

A 27 year old man is brought to the Emergency Department following a suspected deliberate overdose. On arrival he is drowsy with a GCS of 13/15 (E3V4M6) and confused. His airway is currently patent. The respiratory rate is 30 breaths per minute although oxygen saturations are 98% on 2L/min oxygen. The chest is clear to auscultation. Heart rate is 108bpm and blood pressure is 96/48mmHg. The ECG shows sinus tachycardia only. He complains of severe abdominal pain and is groaning on examination. There is significant tenderness in the right upper quadrant. Bowel sounds are hyperactive. Neurological examination is difficult but discloses downgoing plantars and reactive, mid-size pupils.

Blood tests show:

Haemoglobin	112g/L	Sodium	131mmol/L	Glucose	17.8mmol
MCV	96fL	Potassium	Haemolysed	Lactate	5.3mmol/L
White cells	15.7x10 ⁹ /L	Urea	15.6mmol/L	pH	7.14
Neutrophils	13.7x10 ⁹ /L	Creatinine	207mol/L	pCO ₂	2.9kPa
Platelets	278x10 ⁹ /L	ALP	234U/L	pO ₂	19.2kPa
INR	1.2	ALT	2453U/L	Bicarbonate	9.4mmol/L
PT	14secs	AST	3109U/L	Base excess	-15.4mEq/L
APTT	49.2secs	Bilirubin	36mol/L	Anion gap	30.8

The laboratory comments there is significant haemolysis of the samples.

He has a massive vomit during assessment of black liquid and fresh blood.

Which of the following drugs is this patient most likely to have overdosed upon?

	Aspirin
	Ferrous sulphate

	Ibuprofen
	Paracetamol
	Venlafaxine

Question 61 of 156

□ □

A 75-year-old lady with memory problems attended a specialist memory clinic with her daughter. Her daughter was very concerned and mentioned that her mother had been much more forgetful over the past year. She had left the gas cooker on and occasionally got lost when she walked to the shops. On one occasion she had been found by a neighbour wandering the streets in her dressing gown.

This lady had a family history of Alzheimers disease with both her mother and sister being diagnosed with the condition in their seventies.

On examination she had a Mini Mental State Examination Score of 19/30. Otherwise a full physical examination was unremarkable.

Magnetic resonance of imaging of the brain showed marked atrophy of the medial temporal lobes bilaterally with no evidence of a reversible cause of dementia.

You suspect that this lady has Alzheimers disease and wish to start her on donepezil.

Before starting her on this medication which of the following should you arrange?

<input type="checkbox"/>	Electrocardiogram (ECG)
<input type="checkbox"/>	Chest X-ray
<input type="checkbox"/>	Echocardiogram
<input type="checkbox"/>	Lung function tests
<input type="checkbox"/>	Ophthalmology review

□ Question 65 of 156

A 43-year-old gentleman is admitted to the Emergency Department with a 2-week history of worsening drowsiness and confusion. His wife states that he had initially complained of increased tiredness and had started taking to his bed immediately after arriving home from work. One week ago he stopped going to work altogether and his wife reports that he has been sleeping for most of the day since then. This morning she had difficulty waking him, and when she did manage to rouse him he seemed confused with apparent slurring of his speech.

His past medical history is remarkable for epilepsy and bipolar disorder.

On examination, he is responsive only to pain. His vital signs are within normal limits and examination of the chest is unremarkable. His abdomen is soft, with no obvious tenderness and no organomegaly. Bowel sounds are present.

A set of blood tests are taken:

Hb	152 g/l	Na ⁺	139 mmol/l	Bilirubin	18 µmol/l
Platelets	278 * 10 ⁹ /l	K ⁺	4.3 mmol/l	ALP	117 u/l
WBC	8.1 * 10 ⁹ /l	Urea	5.2 mmol/l	ALT	19 u/l
Neuts	5.4 * 10 ⁹ /l	Creatinine	93 µmol/l	γGT	48 u/l
Lymphs	1.8 * 10 ⁹ /l			Albumin	41 g/l
Eosin	0.2 * 10 ⁹ /l			Ammonia	197 µmol/l

His wife later remarks that his medications have recently been altered by his GP. Which of the following is most likely to be responsible?

	Lithium
	Sodium valproate
	Venlafaxine

	Diazepam
	Quetiapine

□ Question 66 of 156

A 75 year old woman was admitted to the Emergency Department after collapsing in her General Practitioner's surgery. She had been unwell for five days with profuse diarrhoea up to 10 times per day and regular vomiting. Her husband reported that she had been unable to keep down oral fluids for the past two days. There was no history of foreign travel but she had visited her grandson the previous weekend who had been suffering from a vomiting illness. Past medical history was unremarkable except for a hysterectomy at age 55 years for fibroids and a laparoscopic cholecystectomy for biliary colic at age 65 years. The patient takes no regular medications.

The initial assessment of the patient documented in the Emergency Department is detailed below.

Airway: patient's own

Breathing: respiration shallow but no overt respiratory distress; respiratory rate 24 / min; oxygen saturations 100 % (15 L O₂); chest clear and resonant; trachea central

Circulation: very dry mucous membranes; capillary refill time 7 seconds; blood pressure 70/30 mmHg; heart rate 130 / minute regular

Disability: GCS 12; temperature 35.9 oCelsius, pupils equal and reactive to light; spontaneous movements of all limbs; plantars down going bilaterally

Exposure: abdomen soft and generally mildly tender; nil other abnormality

Results from an arterial blood sample (15 L O₂) were as follows.

pH	7.31
PaCO ₂	35 mmHg (reference 32-43)
PaO ₂	162 mmHg (reference 70-100)
Bicarbonate	10.4 mmol / L (reference 20.0-26.0)
Sodium	130 mmol / L
Potassium	3.4 mmol / L

Calcium	2.12 mmol / L (reference 2.20-2.60)
Chloride	105 mmol / L (reference 99-108)
Haemoglobin	12.2 g / dL
Lactate	6.5 mmol / L

During initial assessment, IV access was secured and a 500 mL bolus of 0.9 % saline was given. Repeat observation after initial fluid showed BP 72/34 mmHg with heart rate 126 / minute. The patient remained drowsy.

What is the most appropriate next fluid prescription for this patient?

<input type="radio"/>	1000 mL 0.9 % saline over 60 minutes
<input type="radio"/>	500 mL 0.9 % saline over 15 minutes
<input type="radio"/>	500 mL Gelofusine over 15 minutes
<input type="radio"/>	1000 mL Gelofusine over 60 minutes
<input type="radio"/>	100 mL 20 % human albumin solution over 15 minutes

□ Question 67 of 156

A 30-year-old man was brought in after being found unconscious in a club by his friends. His friends report he may have taken some 'Ecstasy' pills in the club but were unsure how many, and he was confused and agitated prior to being found in the toilet unconscious. His past medical history includes depression, for which he was taking fluoxetine 40mg daily.

On examination, he was drowsy, with a temperature of 39°C, heart rate of 120bpm, respiratory rate of 22 breaths per minute, oxygen saturation of 96% on air, and a blood pressure of 160/98mmHg. He was sweating and had a tremor in his arms. Pupils were dilated, equal and reactive to light. He was hypertonic and hyper-reflexic in his arms and legs.

Investigations

Na+	136 mmol/l
K+	4.6 mmol/l
Urea	10.9 mmol/l
Creatinine	90 µmol/l
Creatine kinase	274 IU/L
Serum bilirubin	14 µmol/l
Serum alkaline phosphatase	105 IU/l
Serum aspartate aminotransferase	20 IU/l
C-Reactive protein	2 mg/l
Haemoglobin	146 g/l
White cell count	$6.6 \times 10^9/L$
INR	1.1

Intravenous fluids were started and a bolus dose of Lorazepam was given. What other medication may be useful to manage this patient?

	Dantrolene
	Buspirone
	Procyclidine
	Dextromethorphan
	Phenelzine

□ Question 68 of 156

An elderly lady brings her 32-year-old lodger into the emergency department after she witnesses him having two generalised seizures, lasting for around 4 minutes before spontaneously terminating, followed by a loss of consciousness lasting for around 10 minutes before slowly becoming rousable again. He is not known to have a history of epilepsy and does not take any regular medications. He denies any history of illicit drugs, smoking or excessive alcohol intake, corroborated by his landlady, who reports not to have seen him ever drinking in the 4 years he has been living in her loft space. Apart from a mild headache, he claims to have been well recently, continuing to work on his start-up computer software in the loft. She states that he has always 'kept himself to himself' in a cluttered dark loft space without a window, with a simple mattress and a small wardrobe. He didn't even ask for an additional heater during the cold winter as he thought 'the loft gas boiler provides enough warmth'. On examination, he is slightly sleepy but rousable. His Glasgow Coma Score is E4 V5 M6. Apart from erythematous lips, you note no other remarkable features. Neurological examination of his cranial nerves, upper and lower limbs are unremarkable. There is no ophthalmoscope available. His observations are heart rate 90/min and regular, BP 132/88 mmHg, sats 98% on air.

His blood tests demonstrate:

Hb	159 g/l
Platelets	$282 \times 10^9/l$
WBC	$7.9 \times 10^9/l$

Na ⁺	143 mmol/l
K ⁺	4.2 mmol/l
Urea	6.1 mmol/l
Creatinine	88 μ mol/l
CRP	3 mg/l

His arterial blood gas demonstrate:

pH 7.25	

PaO2	15.8 kPa
PaCO2	2.9 kPa
Lactate	4.5 mmol/l
HbCO	24%

A CT head demonstrates a small area of acute ischaemic change in the right globus pallidus.

Which is the most appropriate next management?

	High flow oxygen
	Aspirin 300mg
	Clopidogrel 300mg
	PO chlordiazepoxide 40mg QDS
	Start levetiracetam 250mg BD

Question 71 of 156

□ □

A 43 year old man attends for follow up at the Infectious Diseases clinic. He is an HIV-positive patient who has been well while on treatment for the last 13 years. His current treatment regimen is emtricitabine, atazanavir and tenofovir. He has however begun to notice altered taste and a difficulty in swallowing over the last couple of months. In the last few days he has even noticed a white coating in his mouth that is not removed by vigorous scrubbing with his toothbrush. He describes being compliant with his medications and not taking any illicit drugs. He no longer has unprotected sexual intercourse. The only change that is identified is that he recently visited his GP with non-specific symptoms and was started on a new medication.

CD4 count in clinic 4 months ago 526
CD4 count currently 210

What medication is the GP likely to have started?

	Lansoprazole
	Aspirin
	Amitriptyline
	Paracetamol
	Simvastatin

□ Question 74 of 156

A 28-year-old woman attended the emergency department and was subsequently referred to the cardiology team due to concerns about the risk of potential cardiac arrhythmia. The patient presented to the emergency department due to ongoing nausea and vomiting secondary to hyperemesis gravidarum. The patient stated she was 10 weeks pregnant with her first child and had been suffering from these symptoms for the past 6 weeks. Clinical records indicated the patient had also attended the emergency department 3 weeks previously with the same presenting complaint.

On the initial occasion the patient had presented to the emergency department with hyperemesis gravidarum, she had been rehydrated with intravenous fluids and prescribed vitamin B6 and ginger capsules four times daily on the advice of the obstetric team. The patient reported that this treatment had given her only a modest improvement in her symptoms and she had stopped taking these medications after a few days. Subsequently, she had attended an out-of-hours medical centre and been prescribed ondansetron (4 mg three times daily). The patient had found a more significant benefit from ondansetron and had been taking it regularly over the past 2 weeks. In addition to her symptoms of nausea and vomiting, the patient reported feeling tired, lethargic and dehydrated. However, she denied experiencing any other symptoms, including palpitations or pre-syncopal episodes.

The patient's past medical history included a period of intravenous drug use in her early twenties. Three years previously the patient had successfully managed to stop her use of illicit drugs after being enrolled in a methadone treatment program. The patient was now on a consistent methadone dose of 80 mg once daily. There was no other significant past medical history and the patient took no other regular medications.

During the patient's assessment after attending the emergency department, concern was raised over a prolonged corrected QT interval on an ECG performed due to borderline hypokalaemia. The patient's ECG was otherwise unremarkable and was compared to previous ECGs the patient had undergone on her previous visits to the emergency department. Please see below for blood results and data from the patient's current and previous ECG.

Haemoglobin	123 g / dL
Mean cell volume	84.9 fl
White cell count	11.7 x 10 ⁹ / microlitre
Platelets	187 x 10 ⁹ / microlitre
Urea	9.0 mmol / L

Creatinine	82 micromol / L
Sodium	139 mmol / L
Potassium	3.6 mmol / L

Presentation	Relative date of ECG	Corrected QT interval / ms
2nd ED attendance for hyperemesis	Today	490
1st ED attendance for hyperemesis	3 weeks previously	430
Unrelated ED attendance	4 years previously	415

With regard to the patient's prolonged corrected QT interval, what is the most appropriate strategy for managing her medications?

	Continue both methadone and ondansetron and admit for cardiac monitoring
	Stop both methadone and ondansetron
	Continue both methadone and ondansetron and arrange outpatient ambulatory ECG
	Continue methadone, stop ondansetron
	Continue ondansetron, stop methadone

Dashboard

Overall score: **0%**

□ Question 75 of 156

□ □

A 77-year-old woman with a long history of atrial fibrillation comes to the Emergency department following a collapse at the local supermarket. She is treated with digoxin for rate control, and anti-coagulated with warfarin. Apparently she has been unwell with diarrhoea over the past few days but has continued to take her regular medication. On examination her blood pressure is 90/50 mmHg, pulse is 88 beats per minute and regular. You note short runs of ventricular tachycardia on the monitor whilst you are listening to her chest. Bloods include:

Na ⁺	145 mmol/l
K ⁺	3.5 mmol/l
Urea	14.1 mmol/l
Creatinine	188 µmol/l
Digoxin	3 nmol/l

Which of the following is the most appropriate intervention?

	Amiodarone

□ Question 75 of 156

□ □

A 77-year-old woman with a long history of atrial fibrillation comes to the Emergency department following a collapse at the local supermarket. She is treated with digoxin for rate control, and anti-coagulated with warfarin. Apparently she has been unwell with diarrhoea over the past few days but has continued to take her regular medication. On examination her blood pressure is 90/50 mmHg, pulse is 88 beats per minute and regular. You note short runs of ventricular tachycardia on the monitor whilst you are listening to her chest. Bloods include:

Na ⁺	145 mmol/l
K ⁺	3.5 mmol/l
Urea	14.1 mmol/l
Creatinine	188 µmol/l
Digoxin	3 nmol/l

Which of the following is the most appropriate intervention?

	Amiodarone
	Flecainide
	Verapamil
	Magnesium
	Phenytoin

□ Question 76 of 156

A 43 year old man is brought to the Emergency Department by his wife. She has become worried about him in the past six months as he has become increasingly confused, aggressive and depressed. He has also lost 4kg in weight in this time and has developed severe, intermittent abdominal pain and diarrhoea, and complains of constant headaches.

Examination reveals a normal cardiorespiratory examination but the abdomen is diffusely tender and there is tender fullness in the right upper quadrant. Neurological examination reveals minor hypotonia throughout and there are bilateral radial nerve palsies as well as a left common peroneal nerve palsy. Sensation appears intact. He is alert but confused with an abbreviated mental test score of 7/10.

Blood tests reveal:

Sodium	136mmol/L	ALP	135U/L	Haemoglobin	79g/L
Potassium	5.1mmol/L	AST	265U/L	MCV	101fL
Urea	7.1mmol/L	ALT	298U/L	White cells	$9.4 \times 10^9/L$
Creatinine	102 μ mol/L	GGT	197U/L	Neutrophils	$5.6 \times 10^9/L$
CRP	10mg/L	Bilirubin	12 μ mol/L	Lymphocytes	$3.1 \times 10^9/L$
Calcium (corr)	2.34mmol/L			Eosinophils	$0.1 \times 10^9/L$
Phosphate	0.56mmol/L			Basophils	$0.6 \times 10^9/L$
Magnesium	0.76mmol/L				
Glucose	3.8mmol/L				

The blood film shows anaemia with a dimorphic picture, significant reticulocytosis and high basophil numbers with cytoplasmic stippling.

The patients wife tells you all the symptoms coincided with the patient starting a new job as a loading crane driver at a scrap-yard.

What is the most likely diagnosis?

	Chronic alcoholism
	Acute promyelocytic leukaemia
	Porphyria cutanea tarda
	Chronic lead poisoning
	Minimata disease

Dashboard

□ Question 77 of 156

□ □

A 53-year-old woman is called to clinic for review following abnormal blood tests. Two weeks ago her GP increased her dose of ramipril to 10mg from 5mg as her blood pressure was poorly controlled. She has recently had a flare of her rheumatoid arthritis. She feels systemically well and is not dehydrated. Her current medications include ramipril, simvastatin, aspirin, paracetamol, omeprazole and naproxen as needed. She has been taking naproxen for the right five days due to a flare in rheumatoid arthritis

Blood tests:

	26/11/2016	9/11/2016
Na ⁺	139 mmol/l	140 mmol/l
K ⁺	4.6 mmol/l	4.3 mmol/l
Urea	5.5 mmol/l	5.8 mmol/l
Creatinine	85 µmol/l	64 µmol/l

How should her medications be managed?

	Stop naproxen and continue ramipril
	Stop naproxen
	Stop naproxen and stop ramipril
	Reduce the dose of ramipril
	Stop ramipril

Question 78 of 156

□ □

A 68-year-old female accountant on azathioprine for systemic lupus erythematosus (SLE) presented to the rheumatology clinic for her usual yearly follow up. She is clinically well and her blood investigations show stable disease but you note raised serum uric acid. She also volunteers that she intermittently suffers excruciatingly painful, red and swollen joints including her left first metatarsophalangeal joint and right ankle. These episodes improve with diclofenac. She is currently asymptomatic. Based on her symptoms you strongly suspect that she suffers from recurrent episodes of gout.

In the management of gout in this patient, which of the following prescription medications should you strongly avoid?

	Diclofenac
	Allopurinol
	Colchicine
	Probenecid
	Prednisolone

Question 79 of 156

A 57-year-old male is admitted to hospital with an acute kidney injury (AKI). His past medical history includes polycystic kidney disease for which he received a renal transplant 4 years ago, and type 2 diabetes mellitus. His drug history includes tacrolimus, mycophenolate mofetil, amlodipine and simvastatin. Tacrolimus toxicity is suspected to have caused his AKI.

He informs you that he has only recently been discharged, where he was started on rifampicin and erythromycin for Legionnaires' disease. He was also started on pioglitazone after a diabetic team review.

Which of his other medications is the most likely culprit of the tacrolimus toxicity?

	Pioglitazone
	Erythromycin
	Simvastatin
	Rifampicin
	Mycophenolate mofetil

□ Question 80 of 156

A 31 year old man is brought to the Emergency Department from a nightclub. He is accompanied by a friend who tells you he has taken the street drug NRG-1. The patient is agitated and difficult to assess as he will not stay on the trolley. He is sweating profusely and his skin has a blue tinge to it. Formal assessment is impossible but he is obviously confused and appears to be hallucinating. Examination shows a heart rate of 139bpm with a blood pressure of 158/105mmHg. Heart sounds are rapid but with no murmurs. The chest is clear to auscultation and oxygen saturations are 99% on air but his respiratory rate is 36/min. He is globally hypertonic with marked clonus in the lower limbs. Tympanic temperature is 40.6°C.

Blood results show:

Haemoglobin	129g/L	Sodium	119mmol/L	Creatine Kinase	1895ng/mL
Haematocrit	0.29	Potassium	5.5mmol/L	CRP	8.9mg/L
White cells	15.6x10 ⁹ /L	Chloride	90mmol/L		
Neutrophils	11.7x10 ⁹ /L	Urea	7.2mmol/L		
Platelets	303x10 ⁹ /L	Creatinine	100µmol/L		

Urine is dilute but contains blood, protein and ketones on dipstick analysis

Which one of the following interventions is the most appropriate in the first instance?

	Rapid intravenous infusion of 0.9% sodium chloride with 1g IV paracetamol
	Rapid intravenous infusion of 3% sodium chloride with 1g IV paracetamol
	Slow intravenous infusion of 3% sodium chloride with 10mg IV midazolam
	Slow intravenous infusion of 3% sodium chloride with 1g IV paracetamol and oral cyproheptadine 12mg
	Intravenous methylene blue (methylthioninium chloride) 1mg/kg over 5 minutes

□ Question 81 of 156

A 19 year old woman is brought to the Emergency Department by ambulance following a deliberate overdose of imipramine tablets.

On primary assessment, the airway is stabilised with a Guedel oropharyngeal adjunct. Breaths are shallow with a rate of 20 and oxygen saturations are 96% on 15L/min oxygen via non-rebreathe mask. Blood pressure is 72/44mmHg with a heart rate of 127bpm. Cardiac monitoring reveals a wide complex tachycardia. The GCS is depressed at 6/15 with widely dilated pupils, hypertonia, hyperreflexia and upgoing plantars.

An arterial blood gas sample reveals:

pH	7.00	Potassium	4.5mmol/L
pCO ₂	7.12kPa	Chloride	97mmol/L
pO ₂	19.8kPa	Lactate	3.8mmol/L
HCO ₃ ⁻	3.7mmol/L	Glucose	8.4mmol/L
BE	-24.5mmol/L		

The patient is intubated and ventilated on mandatory positive pressure ventilation and aggressively fluid resuscitated. She is infused with 150ml 8.4% sodium bicarbonate solution and within 15 minutes the pH is 7.27. The blood pressure remains below 80mmHg systolic and the ECG still shows broad complex tachycardia but a normal QT interval.

Which intervention is the next most appropriate?

	5g (20mmol) magnesium sulphate intravenously
	300mg amiodarone loading with 900mg infusion over 24 hours
	20% lipid emulsion bolus with 500ml infusion over 1 hour
	100J synchronised DC shock

Dashboard

Question 82 of 156

□ □

A 63-year-old woman returns to neurology clinic for review with her husband. She was diagnosed with Parkinson's disease two years ago and was started on ropinirole six months ago as her symptoms were becoming difficult to manage. She was mainly concerned with the rigidity of her movements. Since then she has improved remarkably, and her movements are much better, with reduced rigidity on examination. Her mood has also been improving with the relief from her symptoms.

However, her husband has become concerned that she has been increasingly spending large amounts on shopping, something which has not done before and that he feels is out of character. What is the most likely explanation?

	Normal behaviour
	Progression of Parkinson's disease
	Lewy-body dementia
	Dopaminergic dysregulation syndrome
	Impulse control disorder

Question 83 of 156

You are the medical basic specialist trainee on call and have been asked to see a gentleman who has just been admitted for a bad chest infection. According to the ward nurse, he has developed an allergic reaction after five minutes of vancomycin i.v infusion.

On arrival you proceed to examine this young man who is febrile, obviously unwell and receiving oxygen via nasal prongs. He claims he had not developed any new symptoms since admission but felt sudden warmth and flushing few minutes into his vancomycin drip. On examination he has crepitations in his left base.

Apart from generalised erythema he appears to be stable and there is no immediate danger to his airways. His blood pressure was 105/67mmHg, pulse was 99b/min and oxygen saturation on 4L oxygen was 95% (all observations are similar to previous readings). He has never taken vancomycin but states he is allergic to penicillin and ciprofloxacin.

Given the likely diagnosis, what is the next step in your management?

<input type="checkbox"/>	Immediately stop vancomycin
<input type="checkbox"/>	Continue vancomycin but at a slower rate
<input type="checkbox"/>	Continue vancomycin rate unchanged
<input type="checkbox"/>	Administer i.v chlorphenamine maleate and stop vancomycin
<input type="checkbox"/>	Urgent i.m adrenaline

Question 84 of 156

A 31-year-old ICU nurse is brought to the Emergency Department following an unresponsive episode during a busy shift at work. His colleague described him becoming pale and sweating profusely, before collapsing to the ground and becoming unresponsive. No jerking movements were observed.

His past medical history is unremarkable and he takes no regular medications.

On examination, the patient is pale and sweaty. His GCS is 9/15. His pulse is 106bpm and his blood pressure is 118/67mmHg. His chest is clear and his abdomen is soft and non-tender. There are linear, well-healed scars over the volar aspects of both forearms. His capillary blood glucose measurement is 1.6 mmol/l.

The patient is given 250ml of 10% dextrose solution through a large-bore peripheral venous cannula and his GCS improves to 15/15. His initial blood test results are:

Hb	135 g/l	Na ⁺	139 mmol/l
Platelets	221 * 10 ⁹ /l	K ⁺	3.5 mmol/l
WBC	7.1 * 10 ⁹ /l	Urea	4.8 mmol/l
Neuts	5.3 * 10 ⁹ /l	Creatinine	81 µmol/l
Lymphs	1.2 * 10 ⁹ /l	CRP	13 mg/l
Eosin	0.03 * 10 ⁹ /l		

Glucose	1.2 mmol/l
Insulin	254 pmol/l (<174 pmol/l)
C-peptide	1.8 nmol/l (0.26 - 1.03 nmol/l)

What is the most likely cause of the hypoglycaemia?

Exenatide poisoning

	Insulin poisoning
	Insulinoma
	Sulfonylurea poisoning
	Hepatic glycogen depletion due to missed meal breaks

□ Question 85 of 156

A 34-year-old male was admitted after being found on the floor. He admitted to drinking too much alcohol, and had taken cannabis and inhaled nitrate based poppers' with his friends. He is a long term heavy smoker, and was admitted before with alcohol toxicity and other illicit drug use but does not have other past medical history. He was admitted to the Acute Medical Unit because his saturations were only 88- 90% on 10L of oxygen despite being asymptomatic. He had a heart rate of 90 beats/min, blood pressure of 118/80 mmHg, respiratory rate of 14/min and was noticed to have peripheral cyanosis. On auscultation, there was very mild scattered wheeze, but otherwise good air entry. The arterial blood gas on air revealed the following:

pH	7.36
pCO ₂	5.8 kPa
pO ₂	10.8 kPa

Question 85 of 156

A 34-year-old male was admitted after being found on the floor. He admitted to drinking too much alcohol, and had taken cannabis and inhaled nitrate based poppers' with his friends. He is a long term heavy smoker, and was admitted before with alcohol toxicity and other illicit drug use but does not have other past medical history. He was admitted to the Acute Medical Unit because his saturations were only 88- 90% on 10L of oxygen despite being asymptomatic. He had a heart rate of 90 beats/min, blood pressure of 118/80 mmHg, respiratory rate of 14/min and was noticed to have peripheral cyanosis. On auscultation, there was very mild scattered wheeze, but otherwise good air entry. The arterial blood gas on air revealed the following:

pH	7.36
pCO2	5.8 kPa
pO2	10.8 kPa
HCO3-	22 mmol/l
BE	-2.4 mmol/l
Sats	90%
MetHb	16%
Na	136 mmol/l
K	4.6 mmol/l
Lactate	1.8 mmol/l

What is the most appropriate management?

□ Question 86 of 156

□ □

A 54-year-old woman was admitted following abnormal blood tests on routine monitoring. She is currently undergoing palliative chemotherapy with FOLFIRINOX, a combination of folinic acid, fluorouracil, irinotecan and oxaliplatin for metastatic pancreatic cancer. She has suffered from diarrhoea, vomiting, nausea and fatigue since starting treatment. She has a past medical history of hypothyroidism, epilepsy and bipolar disorder. Her regular medications include levothyroxine, levetiracetam, lithium, loperamide, paracetamol, oramorph, zomorph, movicol and ondansetron.

Na ⁺	142mmol/l
K ⁺	3.8mmol/l
Urea	4.4mmol/l
Creatinine	83μmol/l
Corrected calcium	3.3μmol/l

She is started on treatment with IV 0.9% saline and given 90mg of IV alendronate after further blood tests are sent for, and an ECG is done. Which of her regular medications should not be prescribed on admission?

	Zomorph
	Levetiracetam
	Loperamide
	Levothyroxine
	Lithium

□ Question 87 of 156

You are asked to review a 44-year-old lady in the emergency department. She is well known to the mental health liaison team because of her multiple suicide attempts. She is agitated and slightly confused and unable to give a precise history. She is able to tell you that she can't see clearly and has a dry mouth.

Her sister explains that the patient has been prescribed medicines for chronic neuropathic back pain and has taken them all after splitting up with her boyfriend.

On examination she has symmetrically dilated pupils but no focal motor deficit. Her heart sounds are normal and her lung fields are clear on auscultation. An ECG shows sinus tachycardia with a QRS of 170.

Bloods results are as follows:

Hb	125 g/l
Platelets	$440 \times 10^9/l$
WBC	$9.9 \times 10^9/l$
Na ⁺	135 mmol/l
K ⁺	4.2 mmol/l
Urea	5.1 mmol/l
Creatinine	88 μ mol/l
Plasma Paracetamol	<5mmol/l

You request an arterial blood gas which shows the following readings:

pH	7.29
pCO ₂	3.4 kPa
pO ₂	14.5 kPa

What is the most appropriate next step in this patient's management?

	IV sodium bicarbonate
	Haemodialysis
	IV lignocaine
	IV amiodarone
	Naloxone

□ Question 91 of 156

□ □

A 45 woman is admitted with fever, night sweats and weight loss. She has a past medical history of type 1 diabetes. At a recent retinal screen there were microaneurysms and dot and blot haemorrhages noted on the periphery of both her discs. She has never noted any visual problems.

A sputum sample is positive for acid fast bacilli and she is subsequently started on Rifampicin, Isoniazid, Pyrazinamide, ethambutol and pyridoxine.

On the same admission she is diagnosed with HIV. Her CD4 count is 140 cells/ μ L. She is started cotrimoxazole and a few weeks later starts antiretroviral therapy with Efavirenz, emtricitabine and tenofovir.

She makes a good recovery and is discharged from hospital. A few months later she complains of increasingly blurry vision. Fundoscopy shows pale optic discs, microaneurysms and blot haemorrhages.

What is the most likely cause for her visual symptoms?

	CMV retinitis
	Ethambutol
	Efavirenz
	Diabetic retinopathy
	Pyrazinamide

Question 95 of 156

A 17-year-old girl is brought to the Emergency Department by ambulance after her drink was 'spiked' at a party. Her friends recall her complaining that she felt like she was having an 'out of body experience' and that everything she touched seemed artificial. Over the next hour, she became increasingly distressed, slurring her words and appearing off-balance when walking.

Her past medical history is unremarkable. Her friends state that she does not usually partake in recreational drug use and had only consumed 2 or 3 alcoholic drinks during the course of the evening.

Examination reveals a slim young female with a temperature of 37.3, a pulse of 113bpm and a blood pressure of 137/76mmHg. Her pupils measure 5mm in diameter and she is GCS 14/15 due to persistent confusion. Her chest is clear and her heart sounds are unremarkable. Her abdomen is soft and non-tender. Neurological examination reveals bi-directional nystagmus and truncal ataxia with no focal weakness. Her deep tendon reflexes are brisk and symmetrical.

Which drug is she most likely to have been exposed to?

	Ecstasy
	Methoxetamine
	Cocaine
	Gamma-hydroxybutyric acid (GHB)
	Nexus (2C-B)

Dashboard

Question 101 of 156

A 68-year-old gentleman presents acutely with a hot, red, swollen and painful right big toe. This has happened twice before, some years ago, and he has never sought medical attention. He has a raised serum urate level and joint fluid analysis demonstrates negatively birefringent needle-shaped crystals. Once symptoms settle he is started on allopurinol but develops a severe hypersensitivity reaction to this. Which agent should be tried next as a long-term treatment option?

	Colchicine
	Naproxen
	Febuxostat
	Methotrexate
	Prednisolone

□ Question 102 of 156

□ □

A 22 year old woman is brought to the Emergency Department by ambulance. She is accompanied by her boyfriend who tells you he thinks she has taken a deliberate overdose of up to 80 fluoxetine tablets (20mg) within the past eight hours. On assessment her airway is patent but threatened with a respiratory rate of 26 and peripheral oxygen saturations of 97% on air. Her chest is clear. The heart rate is 118bpm and the blood pressure is 98/39mmHg. Capillary blood glucose is 5.0mmol/L. The ECG shows a sinus tachycardia with QRS duration 114msec and corrected QT interval 575msec. She is globally hypertonic, shivering, nauseated, vomiting and sweaty with a tympanic temperature of 37.7°C and dilated pupils and prominent clonus. She suddenly has a prolonged tonic-clonic seizure and receives 20mg intravenous diazepam with no response after 15 minutes.

Which of the following is the safest subsequent intervention in this patients management?

	Further 10mg intravenous diazepam
	10mg rectal diazepam
	Phenytoin infusion 20mg/kg
	Levetiracetam 1000mg intravenous infusion
	Intubate and ventilate

□ Question 103 of 156

A 52-year-old male presents to the emergency department with a 5-week history of constipation not relieved by over the counter laxatives. His past medical history was significant for hypertension, COPD and schizophrenia. His current medications include ramipril, clozapine and tiotropium. He denied weight loss, poor appetite or other alarming symptoms. His family history was significant for bowel cancer with his father and uncle having died of colon cancer aged 78 and 82 respectively. His sister had a hysterectomy at the age of 72 but he was not sure why. On examination, his blood pressure was 124/78mmHg lying and 115/80mmHg standing. Pulse was 63/min. Clinical examination did not reveal any significant findings.

Investigations:

Hb	137 g/l
MCV	82 fl
Platelets	420 * 10 ⁹ /l
WBC	7 * 10 ⁹ /l
Creatinine	89 umol/L
Urea	4.7 umol/L
Na+	143 mmol/L
K+	3.9 mmol/L
Corrected Calcium	2.3mmol/L
FOB	negative
Abdominal X-ray	faecal loading

What is the most likely cause of constipation in this case?

	Clozapine

	Colon cancer
	Illicit drugs
	Dehydration
	Malingering

Dashboard

A 52-year-old farmer was brought into the Emergency Department by his wife. Over the last few hours, he developed severe diarrhoea, passing 10 loose stools in the last four hours. He was also passing urine more frequently and on a couple of occasions was incontinent of urine. He also complained of feeling unwell with a headache and nausea and as well as a cough with white phlegm, and at times felt very short of breath particularly upon coughing. He denied the presence of chest pain. He had a past medical history of COPD, atrial fibrillation, depression and hypertension and his drug history comprised of Seretide 2puffs BD, salbutamol PRN, digoxin 250mcg OD, warfarin 2mg OD, sertraline 150mg OD, diazepam 2mg BD PRN and amlodipine 5mg OD.

Examination revealed the presence of an unwell and unkempt gentleman. His heart rate was 46 bpm and regular, his blood pressure was 88/48mmHG, his respiratory rate was 18, oxygen saturations 96% on air and temperature 35.7°C. His BM was 3.8 mmol/l. Examination of his cardiovascular system revealed the presence of warm well perfused peripheries with normal heart sounds and a JVP of 3cm. Examination of his respiratory system revealed the presence of copious upper airways secretions but the absence of respiratory distress. Examination of his gastrointestinal system revealed the presence of excess salivation but was otherwise unremarkable. Examination of his neurological system revealed the presence of bilateral pupil constriction but otherwise no abnormalities and a GCS of 15.

He was promptly transferred to the resuscitation area and cannulated with 2 large bore cannulae. Stat intravenous saline 3 litres were promptly infused and an urgent medical consult was requested. Initial investigations revealed the following:

Hb	140 g/l
Platelets	198 * 10 ⁹ /l
WBC	6.6 * 10 ⁹ /l
CRP	4 mg/l

Coagulation screen: INR 2.2, APTT and fibrinogen within normal limits

Portable chest x-ray: poor quality rotated film. Normal appearance of heart and lung fields.

ECG: sinus bradycardia heart rate 45bpm, normal sinus rhythm, normal QRS and QTc intervals, no acute ST/T changes

Arterial blood gases on air:

pH	7.33
PaO2	12.6 KPa
PaCO2	5.8 kPa
HCO3	18 mmol/l
BE	-4

Of the following options which is the most appropriate curative management step?

	Commence digoxin fragment binding antibody (Digibind)
	Commence broad spectrum intravenous antibiotics and instigate sepsis protocol
	Commence intravenous noradrenaline
	Commence intravenous flumazenil
	Commence intravenous atropine

Question 105 of 156

□ □

A 45-year-old gentleman is advised by his GP to attend hospital following a routine blood test demonstrating an increase in creatinine two weeks following a dose increase in his ramipril. His ramipril was increased from 5mg daily to 5mg twice a day.

He has a letter which demonstrates investigation results, shown below. He reports no new symptoms. He reports that home monitoring of blood pressure has shown his control to be better.

	21/11/2016	6/11/2016
Na ⁺	140 mmol/l	138 mmol/l
K ⁺	4.5 mmol/l	4.1 mmol/l
Urea	5.5 mmol/l	5.4 mmol/l
Creatinine	110 µmol/l	92 µmol/l

How should his ramipril be managed and monitored?

	Continue ramipril and repeat U&Es in 1-2 weeks
	Reduced the dose of ramipril and repeat U&Es in 1-2 weeks
	Stop ramipril and repeat U&Es in 1-2 weeks
	Stop ramipril and arrange for an urgent out-patient imaging to exclude renal artery stenosis
	Continue ramipril and repeat U&Es within 48 hours

□ □

A 56 year old gardener is brought to the Emergency Department by his wife. He was bitten on the right hand by a snake while clearing bushes in his back garden. It is identified as a common European adder. There is an obvious, red puncture site on the dorsum of the right hand with significant swelling of the entire hand to the level of the wrist. He is in significant discomfort. Examination reveals a normal cardiovascular examination with a heart rate of 112bpm, blood pressure of 137/90mmHg and normal respiratory rate and oxygen saturations. Capillary glucose is 5.6mmol. ECG shows normal sinus rhythm with normal PR, QRS and QT intervals. Routine blood tests including liver function, electrolytes, creatine kinase, full blood count and arterial blood gases are normal.

Which of the following interventions is the most appropriate at this stage?

	Application of a tourniquet above the site of envenomation to prevent systemic toxicity
	Bathe the site of envenomation in hot, sterile water to inactivate the venom
	Intravenous access and rapidly infuse 0.9% sodium chloride with 1g intravenous paracetamol
	Intravenous access and administer 200mg IV hydrocortisone, 10mg IV chlorphenamine and 0.5mg IM adrenaline 1:1000
	Intravenous access and administer 10ml adder antivenin in 500ml 0.9% sodium chloride over 30 minutes

A 62-year-old woman is reviewed prior to discharge by the medical team. She was admitted with a lower respiratory tract infection. She now feels well and is ready for discharge. She has a background of type two diabetes mellitus, hypertension, hypothyroidism, osteoarthritis and dementia. Her medication history includes metformin 500mg BD, ramipril 2.5mg OD, levothyroxine 75g OD and paracetamol 500mg QDS PRN. On the first two days in hospital, her metformin was stopped, but her other medications continued as in the community during her admission.

It is noted that she has persistently high blood pressure despite being confirmed as taking ramipril. What is the most appropriate plan to control her hypertension?

	Increase the dose of ramipril and check U&Es within 1-2 weeks
	Increase the dose of ramipril and check U&Es within 3-4 weeks
	Add amlodipine, increase the dose of ramipril and check U&Es within 3-4 weeks
	Add on amlodipine at a low dose
	Stop ramipril and start amlodipine instead

A = ACE inhibitor

C = Calcium channel blocker

D = Thiazide Diuretic

Question 115 of 156

□ □

An 18-year-old female presents with collapse. Her bloods show-

Hb	112 g/l
Platelets	$324 \times 10^9/l$
WBC	$4.2 \times 10^9/l$
Na ⁺	130 mmol/l
K ⁺	2.4 mmol/l
Urea	8.9 mmol/l
Creatinine	109 μ mol/l
CRP	0.5 mg/l

Her blood pressure is 77/38 mmHg and heart rate 121 beats per minute. Her only past medical history is anorexia and self-harm and she is minimally cooperative with any attempt at a history or examination.

Which of these is the most likely cause for her presentation?

	Pseudohypoaldosteronism
	Familial hyperaldosteronism type 1
	Addison's disease
	Furosemide abuse
	Aldosterone-producing adenoma

Overall score: **0%**

Question 116 of 156

□ □

A 53 year old patient has undergone six cycles of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisolone) chemotherapy and is now attending the lymphoma follow up clinic. He complains of an ongoing and unrelenting tingling in his feet and legs as well as his right hand. This is associated with pain in the extremities that is worsened by the cold weather.

Examination reveals normal motor strength throughout all 4 limbs but marked reduction in proprioception in both legs below the knee and also the right hand. There is a 'glove and stocking' distribution of loss when tested for pin-prick sensation and a reduced joint position sense to the ankle in both lower limbs. Plantar reflexes are normal. During the examination you it is noted that the patient has sustained an injury to the sole of foot which he was unaware of.

What is the most likely causative agent for these symptoms?

	Rituximab
	Cyclophosphamide
	Doxorubicin
	Vincristine
	Prednisolone

Question 117 of 156

A 29 year old man is brought to the Emergency Department by ambulance after being found collapsed at home by his father. The patient had a known history of major depression and was found next to two empty bottles of fluoxetine which he had been prescribed by his psychiatrist. His father reported that he had found a suicide note at the patients home.

On arrival in hospital the patient was extremely agitated and unable to give a clear history. Initial assessment was as documented below.

Airway

- Patient's own

Breathing

- Respiratory rate 28
- Some increased work of breathing
- O2 saturation 100 % (10 L via non-rebreath mask)
- Air entry throughout chest with vesicular breath sounds

Circulation

- BP 190 / 100 mmHg
- HR 120 bpm, pulse regular
- JVP not elevated
- Heart sounds normal

Disability

- Temperature 38.4°C
- Flushed and sweaty
- Patient agitated and distressed
- Pupils equal and reactive
- Rapid, involuntary horizontal and vertical conjugate fast eye movements
- Good power in all arms and legs 10 beats of clonus on ankle dorsiflexion, mild increase in general muscle tone Reflexes very brisk and symmetrical in arms and legs

Exposure

- Abdomen soft and non-tender

Results from arterial blood sample (10 L O₂) were as follows

pH	7.35
PaCO ₂	30 mmHg (reference 32-43)
PaO ₂	159 mmHg (reference 70-100)
Bicarbonate	22.5 mmol / L (reference 20.0-26.0)
Sodium	139 mmol / L
Potassium	4.5 mmol / L
Lactate	2 mmol / L

Electrocardiogram: sinus rhythm at 125 bpm, normal axis, normal QRS, no acute ST / T wave changes

Portable chest x-ray: clear lung fields, no pneumothorax, no rib fractures

Treatment with intravenous fluids and oral diazepam was initiated following primary assessment. A fan was used to help cool the patient. On review 30 minutes later, the patient remained agitated and distressed with persistent clonus and uncontrolled eye movements only slightly improved to previous assessment. Temperature was 38.1 oC

What is appropriate next line treatment for this patient?

	Intravenous chlorpromazine
	Oral cyproheptadine
	Intubation and ventilation
	Further oral diazepam
	Cooling blanket

□ Question 119 of 156

□ □

A 63 year old farmer is brought to the Emergency Department after falling into a trough of organophosphate sheep dip. On arrival in the department he is in extremis with profuse vomiting and productive of copious respiratory secretions. His airway is threatened but he is also agitated and difficult to assess. Respiratory rate is 20 breaths per minute and oxygen saturations are 87% on 4L/min oxygen. Wheeze is audible from the end of the bed. The heart rate is 55bpm and the blood pressure is 92/44mmHg. Heart sounds are normal. He is incontinent of urine and faeces and has severe abdominal pain. There is widespread muscle fasciculation and global weakness. Pupils are pinpoint.

Which of the following best describes the toxic action of organophosphate compounds?

	Adrenergic blockade due to competitive inhibition of α 1, α 2, β 1 and β 3 receptors
	Adrenergic upregulation due to inhibition of monoamine oxidase
	Cholinergic upregulation due to inhibition of acetylcholinesterase
	Cholinergic upregulation due to direct activation at muscarinic M1, M2 and M3 receptors
	Cholinergic upregulation due to direct activation at nicotinic CNS and muscle receptors

Question 120 of 156

□ □

A 48-year-old female presented with general fatigue, and nausea. She denies having pyrexia, vomiting diarrhoea or any pains. She appeared dehydrated but otherwise, observations and physical examination were within normal limits.

Blood results are as follows:

Na ⁺	130 mmol/l
K ⁺	4.8 mmol/l
Urea	18 mmol/l
Creatinine	162 µmol/l
Lithium	1.6 mmol/l (0.4-1.0 mmol/l)

Looking back at past results from 3 weeks ago, her renal function was in the normal range.

She has a history of bipolar disorder, diet-controlled diabetes and hypertension. She has been compliant with her lithium tablets and undergoing regular checks for the levels.

The patient revealed that her General Practitioner had recently started her on a new tablet 2 weeks ago.

Which of the following would most likely be the precipitant for her symptoms?

	Indapamide
	Amlodipine
	Dihydrocodeine
	Spironolactone
	Propranolol

Question 121 of 156

□ □

A 67 year old man is admitted to the Emergency Department following a deliberate overdose of an unknown drug. On assessment he is unwell and vomiting although he is maintaining an airway. Oxygen saturations are 100% on 15L/min supplemental oxygen and his respiratory rate is 32/min. His chest is clear and heart sounds are rapid. An ECG shows sinus tachycardia with a rate of 135bpm, a broad QRS complex and a QTc 520msec. His skin is flushed and hot. He complains of ringing in his ears and visual blurring as well as abdominal pain. Tympanic temperature is 37.5°C.

Blood results show:

Haemoglobin	101g/L	Sodium	131mmol/L	pH	7.11
White cells	$7.8 \times 10^9/L$	Potassium	2.9mmol/L	pCO ₂	2.4kPa
Platelets	$97 \times 10^9/L$	Urea	9.3mmol/L	pO ₂	78.4kPa
INR	1.3	Creatinine	198μmol/L	HCO ₃ ⁻	6.3mmol/L
APTT	33secs	Glucose	2.8mmol	BE	-19.7
		Chloride	94mmol/L	Lactate	2.4mmol/L

During assessment he has a generalised tonic-clonic seizure.

Which of the following drugs is he most likely to have overdosed on?

	Ibuprofen
	Isocarboxazid
	Paracetamol
	Quinine
	Venlafaxine

Question 122 of 156

□ □

An 82-year-old man presents with pain following a fall. He was brought in by ambulance after he slipped and hurt himself on the pavement. He ended up tripping whilst returning from the local shops. He remembers his fall and noted immediate pain in his right leg, and was unable to get up. A passerby called an ambulance and he was brought into the hospital. He has a past medical history of ischaemic heart disease, mild dementia, hypertension and high cholesterol.

Pelvic X-rays demonstrated an intertrochanteric right hip fracture. He is due to be operated on within the five hours and is put nil by mouth and started on IV fluids. How should his risk of venous thromboembolism (VTE) be managed?

	Low molecular weight heparin before surgery
	Unfractionated heparin before surgery
	Delay VTE prophylaxis until following surgery
	Mechanical VTE prophylaxis before surgery
	IV heparin infusion until surgery

Question 123 of 156

□ □

A 70 year old woman is brought by ambulance to the Emergency Department after being found unresponsive by her husband. He reported that he had been unable to wake the patient from sleep that morning. He said that she had been previously very well without significant physical medical problems. Her only regular medication was moclobemide which she had taken for many years after an episode of severe depression. The patients husband had recently been prescribed fluoxetine for an anxiety disorder, although the patient had also been taking this medication for a few days as she felt her mood had been low.

Initial assessment in hospital showed the patient to be extremely unwell with hypertension (blood pressure 190/110 mmHg). and tachycardia (heart rate 130 bpm). She was minimally responsive with severe rigidity of skeletal muscles. Temperature was recorded as exceeding 40°C.

An urgent anaesthetic review was requested and the patient was intubated and ventilated prior to transfer to the intensive care unit. A plan was made for treatment with IV chlorpromazine.

What action is necessary prior to IV chlorpromazine treatment?

	Intravenous midazolam infusion
	Cardiac monitoring
	Active cooling with ice packs
	Intravenous fluid loading
	Haemodialysis

□ □

A 59- year- old male presented with palpitations, excessive sweating and weight loss for two months. Two years ago he was diagnosed with atrial fibrillation and commenced on amiodarone.

On examination, his pulse rate is 80 beats per minute, irregularly irregular, and his blood pressure is 135/80. There was no goitre, no eye signs or hand signs.

Investigations reveal:

Serum free T4	60 pmol/l
Serum free T3	15 pmol/l (5 - 10)
Serum TSH	<0.05 mU/l
Serum antithyroid peroxidase	negative
TSH receptor antibodies	negative

Radioactive iodine uptake scan showed reduced uptake by the thyroid gland.

What is the most appropriate management for this patient?

	Discontinue amiodarone and give carbimazole
	Discontinue amiodarone and give potassium perchlorate
	Discontinue amiodarone and give prednisolone
	Radioactive iodine
	Total thyroidectomy

Overall score: **0%**

You are asked to review a patient on the ward who the nurse feels is looking very flushed. The nurse noticed the change in the patient whilst they were receiving their first dose of vancomycin. On examination the patient has no symptoms or signs of cardiorespiratory distress. Observations are as follows:

Temperature 37.2 °c
 Respiratory rate 18 breaths/min
 Saturations on air 97%
 Heart rate 70 beats/min
 Blood Pressure 136/72 mmHg

A blanching macular rash is evident on the patient's upper arms and upper thighs. No signs of urticaria or excoriations. The patient is penicillin allergic.

What is your next step?

<input type="radio"/>	Measure mast cell tryptase levels
<input type="radio"/>	Stop the infusion, give the patient piriton and hydrocortisone
<input type="radio"/>	Stop the infusion and give the patient piriton, hydrocortisone, adrenaline
<input type="radio"/>	Continue the infusion but slow it down and give the patient piriton
<input type="radio"/>	Stop the infusion, do not give any further treatment but discuss an alternative antibiotic with microbiology

Saturations on air 97%
Heart rate 70 beats/min
Blood Pressure 136/72 mmHg

A blanching macular rash is evident on the patient's upper arms and upper thighs. No signs of urticaria or excoriations. The patient is penicillin allergic.

What is your next step?

	Measure mast cell tryptase levels
	Stop the infusion, give the patient piriton and hydrocortisone
	Stop the infusion and give the patient piriton, hydrocortisone, adrenaline
	Continue the infusion but slow it down and give the patient piriton
	Stop the infusion, do not give any further treatment but discuss an alternative antibiotic with microbiology

Question 128 of 156

□ □

A 55-year-old man presents to the Emergency Department after taking an overdose. He can not tell you which of his regular tablets he has taken an overdose of. His past medical history includes Crohn's disease, gastroesophageal reflux disease, hypertension, gout, depression and paroxysmal atrial fibrillation.

He is complaining of chest pain and shortness of breath. Observations - respiratory rate 26/min, saturations 94% on air, heart rate 50/min, blood pressure 75/40 mmHg, temperature 37.2°C.

His ECG shows atrial fibrillation with a broad QRS.

Which drug is the most likely culprit?

	Flecainide
	Amitriptyline
	Allopurinol
	Azathioprine
	Diltiazem

□ Question 130 of 156

□ □

A 23-year-old male is brought to the ED via ambulance after a seizure. His friends reported an episode of jerking of all four limbs lasting 1-2 minutes associated with urinary incontinence.

He has vomited twice in the ED and is complaining of muscle aches.

On examination the patient is agitated, confused and appears to be hallucinating. Myoclonic jerks are present. The chest is clear to auscultation and oxygen saturations are 98% on room air. Heart sounds are normal, the pulse rate is 130bpm and the blood pressure is 161/84mmHg.

An ECG reveals sinus tachycardia. The pupils measure 8mm and are equal and reactive. The patient's temperature is 36.6°C.

Blood tests reveal:

Hb	138 g/l
Platelets	362 * 10 ⁹ /l
WBC	11.2 * 10 ⁹ /l
Na ⁺	135 mmol/l
K ⁺	2.7 mmol/l
Urea	12.6 mmol/l
Creatinine	187 µmol/l
Bilirubin	18 µmol/l
ALP	98 u/l
ALT	53 u/l
γGT	27 u/l
Albumin	32 g/l

What is the most likely cause for this patient's presentation?

	Toluene solvent toxicity
	Amyl nitrate toxicity
	Gamma hydroxybutyric acid toxicity
	Synthetic cannabinoid toxicity
	Heroin toxicity

□ Question 133 of 156

A 25-year-old woman attends neurology clinic for on-going follow-up of her epilepsy. She had been diagnosed with generalised epilepsy 7 years previously, following a series of generalised tonic-clonic seizures. At the time of diagnosis, no specific cause for the patient's seizures had been identified. Since the patient's diagnosis, she had trialled a number of treatment combinations, with good seizure control achieved around 4 years after diagnosis.

During clinic review today, the patient declared herself in good general physical health. Her epilepsy continued to be well controlled, with one seizure in the past year and none in the previous 6 months. She also discussed her plans to start a family in the coming months and wanted to know if her current treatment regime would be safe during pregnancy. The patient explained that she had been reading about the risks of epilepsy drugs in pregnancy, and would be keen to alter her treatment regime to minimise the risks to her baby, even if that meant the patient experiencing an increase in seizure frequency.

The patient's previous experience with antiepileptic medications was discussed. The patient had been settled on a regime of lamotrigine 150 mg twice daily and topiramate 200 mg twice daily for the previous 2 years, and had not experienced any significant unwanted effects during this time. At the time of her epilepsy diagnosis, she had initially been treated with lamotrigine monotherapy, which failed to provide adequate seizure control. Subsequently, levetiracetam had been trialled as an adjunctive therapy but was poorly tolerated due to gastrointestinal symptoms and anorexia. Topiramate was then trialled as an adjunctive therapy with success, with titration of doses to the levels described above.

The patient took no other regular medications and had no other known drug allergies. She reported using a Mirena coil and condoms for contraception. The patient was employed as a junior solicitor and did not smoke or take any alcohol.

What is the most appropriate strategy to minimise risk to the patient and to the fetus in any future pregnancy?

	Aim for topiramate monotherapy at lowest effective dose
	Aim for lamotrigine monotherapy at lowest effective dose
	Aim for lamotrigine and carbamazepine dual-therapy
	Continue with current medication regime

Aim to stop all antiepileptic medications

Question 137 of 156

□ □

The Emergency Medical Team were summoned by the urology team. A 62-year-old gentleman was admitted to the care of the urology team a few hours ago complaining of haematuria and loin pain. A CT scan of his abdomen revealed the presence of renal calculi and he was being treated conservatively with intravenous saline hydration therapy, as well as intravenous paracetamol 1g QDS and IV morphine 10mg stat boluses when required. Approximately an hour ago he complained of distressing nausea and vomiting and was administered metoclopramide 10mg IV bolus with a good response. However, over the last few minutes he developed severe neck stiffness and was unable to open his eyelids. His jaw was locked and his tongue was protruding. He had a past medical history comprising panic attacks, type 2 diabetes mellitus, hypertension, hypercholesterolaemia, chronic kidney disease stage 3 and osteoarthritis. In addition to the above medication, his drug history included diazepam 2mg TDS PRN, metformin 500mg TDS, gliclazide 80mg OD, ramipril 5mg OD, atorvastatin 20mg ON and naproxen 500mg BD PRN.

Examination revealed the presence of an acutely compromised gentleman. His head was rotated to the left and fixed in position, with a protruding tongue and a fixed locked jaw. His eyelids were closed. His back was arched, his upper limbs were flexed and his lower limbs were extended. He was very distressed but was sustaining respiratory effort with a respiratory rate of 32/min and oxygen saturations of 96% on air. His chest was clear to auscultate and cardiovascular examination was unremarkable except for the presence of a tachycardia of 132 bpm. His blood pressure was 122/78 mmHg. His temperature was 37.4°C. He was unable to speak but seemed to be fully alert. His capillary blood sugar was 8.2.

A 15 litre/min non-rebreathe oxygen mask was attached; he did not tolerate a Guedel airway insertion. Intravenous access was secured.

What is the next single best immediate management step?

	Crash bleep the anaesthetics team to assist in supporting his airway
	Administer IM lorazepam
	Administer IV adrenaline
	Administer IV dantrolene
	Administer IM procyclidine

Dashboard

Question 138 of 156

□ □

A 35 year old woman is brought to the Emergency Department by blue light ambulance unconscious. She is accompanied by a friend who has found her surrounded by empty packets of diazepam, zopiclone and lamotrigine and two empty wine bottles.

On assessment she has a nasopharyngeal airway in situ, placed by the ambulance crew. Respiratory rate is 8 breaths per minute with an oxygen saturation of 97% on 15L/min oxygen via non rebreathe mask. The blood pressure is 95/45mmHg and heart rate is 100bpm. Blood glucose is 6.7mmol/L. She is globally hypotonic but plantars are downgoing. Pupils are size 2 and minimally reactive. GCS is 7/15 (E2V1M4).

Arterial blood gases show:

pH	7.22	HCO ₃ ⁻	18.5mmol/L
pCO ₂	7.19kPa	Base excess	-6.6mmol/L
pO ₂	7.80kPa	Lactate	3.1mmol/L

What is the most appropriate management option?

	200micrograms IV flumazenil
	400micrograms IV naloxone
	12mg cyproheptadine orally
	No intervention necessary - supportive management on the ward
	Intubate and ventilate

Overall score: **0%**

Question 140 of 156

□ □

An 85-year-old female is admitted under the general medical unit with acute thoracic back pain from a T6 crush fracture following a fall. She has a past history of systolic heart failure, depression and osteoporosis.

Her regular medications included aspirin, frusemide, spironolactone, bisoprolol, sertraline and calcium, vitamin D and weekly alendronate. These are continued throughout her admission.

Two days into her admission, the nurses note that she is agitated and a bit confused.

On examination, she looks flushed and is tachycardic with a heart rate of 120 beats/min and is hypertensive with a blood pressure of 185/70 mmHg, but is afebrile. Both her pupils are mildly dilated, she is mildly tremulous and is noted to have deep tendon hyperreflexia with easily inducible clonus.

Use of which of the following analgaesic medication could explain her current symptoms?

	Paracetamol
	Ibuprofen
	Oxycodone
	Tramadol
	Hydromorphone

Question 140 of 156

□ □

An 85-year-old female is admitted under the general medical unit with acute thoracic back pain from a T6 crush fracture following a fall. She has a past history of systolic heart failure, depression and osteoporosis.

Her regular medications included aspirin, frusemide, spironolactone, bisoprolol, sertraline and calcium, vitamin D and weekly alendronate. These are continued throughout her admission.

Two days into her admission, the nurses note that she is agitated and a bit confused.

On examination, she looks flushed and is tachycardic with a heart rate of 120 beats/min and is hypertensive with a blood pressure of 185/70 mmHg, but is afebrile. Both her pupils are mildly dilated, she is mildly tremulous and is noted to have deep tendon hyperreflexia with easily inducible clonus.

Use of which of the following analgaesic medication could explain her current symptoms?

	Paracetamol
	Ibuprofen
	Oxycodone
	Tramadol
	Hydromorphone

□ Question 141 of 156

□ □

A 19 year old man was brought by his friends to the Emergency Department after becoming unwell on a night out. He had collapsed while dancing then felt very anxious and jittery. On close questioning the patient confessed to taking three tablets of ecstasy during his night out. He had also drunk two beers but insisted he had kept himself hydrated with water later on in the evening. The patient had no past medical history and took no regular medications.

Initial assessment was as documented below.

Airway

- Patient's own

Breathing

- Respiratory rate 20 / minute
- No respiratory distress
- O2 saturations 99 % (air)
- Clear lung fields with air entry throughout

Circulation

- Mild-moderate dehydration
- HR 110 bpm regular
- BP 176 / 95 mmHg
- JVP not elevated
- Heart sounds normal

Disability

- Temperature 37.5°C
- GCS 15/15; anxious
- Pupils equal and reactive to light
- Full range of eye movements
- Good power of arms and legs
- Slight increased tone in arms and legs, 6 beats of clonus inducible on angle dorsiflexion
- Generalised hyper-reflexia

Exposure

- Abdomen soft and non-tender
- No evidence of external or bony injury

Results of a venous blood sample are given below.

pH	7.36
Bicarbonate	24.6 mmol / L (20.0-26.0)
Base excess	-0.9 mmol / L
Sodium	136 mmol / L
Potassium	4.5 mmol / L
Lactate	1.8 mmol / L

What is the correct management of this patient?

	Intravenous chlorpromazine
	Oral cyproheptadine
	Oral diazepam
	Intravenous midazolam
	Slow intravenous fluids; observation

□ Question 142 of 156

□ □

A 27 year old well-nourished male electroplater is admitted to hospital with abdominal pain and neurological symptoms. He tells you that he has had worsening symptoms for the past three months with severe central abdominal pain, diarrhoea, vomiting and painful burning sensation in both feet. He also describes increasing clumsiness with loss of manual dexterity and tripping over his feet frequently. He describes dimming of his vision over the past two weeks with a sepia tinge. On examination, there is mild voluntary guarding of the abdomen but no discrete masses and no organomegaly. The cardiorespiratory examination is normal. Examination of the neurological system reveals distal weakness with MRC power grade 4/5 in all limbs but normal proximal power. There is a mild tremor present with his arms outstretched and trunk ataxia. Sensory examination discloses painful paraesthesia in the hands and feet with hyperalgesia. There is a loss of proprioception. The cranial nerves are notable in that a left sixth nerve palsy is present with accompanying diplopia. Visual acuity is reduced to 6/30 bilaterally and eye movements are painful. He has a bilateral ptosis. He is noted to have minimal body hair, including hairless arms and legs, lateral third of the eyebrow and temporal and crown baldness which he tells you occurred in the past month. He also has scaling of the palms and soles, tender glossitis and transverse white lines on all his nails. He is cyclothymic during assessment.

What is the most appropriate management for this patient?

	High dose IV hydrocortisone 200mg three times daily
	High dose IV vitamin B complex (Pabrinex I+II) and folinic acid
	Intravenous immunoglobulins
	Oral Prussian Blue 10g twice daily
	Procaine penicillin (G) 2 million unit daily IM with oral probenecid

□ □

A 61 year old man with a history of bipolar affective disorder presents to the Emergency Department with a 2 week history of feeling unwell. This started off as a coarse tremor in the limbs and has now progressed to slurred speech and disorientation. On examination you find an ataxic gait and myoclonus. His lithium level 2.6. You diagnose lithium toxicity. In addition to bipolar affective disorder, he has a history of rheumatoid arthritis, atrial fibrillation and GORD. Which of the following recent events is most likely to explain the cause of his toxicity?

	Recent addition of carbamazepine to augment lithium
	Recent prescription of naproxen for knee pain
	Recent increase in caffeine intake
	Recent addition of amiodarone for atrial fibrillation
	Recent use of sodium bicarbonate tablets for symptoms of dyspepsia

Question 145 of 156

A 49-year-old woman with a diagnosis of Hashimoto's thyroiditis is seen in clinic with recurrence of lethargy, constipation, cold intolerance and pedal oedema. These symptoms had previously resolved on starting treatment with levothyroxine.

Her co-morbidities include type 2 diabetes mellitus and hypertension. She was also diagnosed with mycobacterium tuberculosis of the lung five months ago. Her current medications are levothyroxine, amlodipine, ramipril, metformin, gliclazide, rifampicin, isoniazid and pyridoxine.

Her temperature is 36.5°C, pulse 55 beats per minute, blood pressure 165/102 mmHg and respiratory rate 15 breaths per minute.

Thyroid function tests showed:

Free thyroxine (T4)	5 pmol/L (10-25)
Free triiodothyronine (T3)	3 pmol/L (5-10)
Thyroid-stimulating hormone	7.2 mU/L (0.4-5.0)

What is the likely cause of her symptoms?

	Vitamin B6 deficiency
	Rifampicin
	Isoniazid
	Non-compliance with medications
	Amlodipine

Question 146 of 156

□ □

You receive a request for a second opinion from a GP who has performed a general physical check on one of their new patients. He is a 54 year old man who is from Thailand. He had been complaining of low mood, fatigue and sensitivity to the cold. His body mass index is 31 kg/m². The following is a list of investigations performed by the GP.

Na ⁺	141 mmol/l
K ⁺	4.8 mmol/l
Urea	9.8 mmol/l
Creatinine	142 µmol/l
CRP	4 mg/l

Bilirubin	14 µmol/l
ALP	86 u/l
ALT	27 u/l
Calcium	2.89 mmol/l
Albumin	39 g/l
TSH	24.0 mU/l
Free T4	0.8 pmol/l
Free T3	0.4 pmol/l

ECG: Heart rate 68, sinus rhythm, QRS width 128ms, flattened T waves V1 to V6

The patient has told the GP that he takes one medication regularly but is unable to give the name. Which medication is most likely to cause the following abnormalities?

Bendroflumethiazide

	Amiodarone
	Lithium
	Carbimazole
	Propylthiouracil

□ Question 147 of 156

A 26-year-old female presented with lethargy, intermittent low grade fever, bilateral wrist pain, pleuritic type chest pain and an erythematous scaly rash perinasally. She had no significant medical history and her family history was significant for an aunt with autoimmune hepatitis and a brother with type 1 diabetes and pernicious anaemia.

Examination reveals a well young lady. Blood pressure 110/78mmHg and pulse 76/min. Abdominal and cardiovascular examination were normal. There was dullness to percussion over both lung bases. She had swelling and tenderness of her wrists. A malar rash on a background of moderate facial acne with some scarring were noted. She gives a history of acne which has improved ever since she started taking minocycline prescribed by her GP 3 months ago. She is also on oral contraceptives for irregular periods.

Investigations:

Hb	10.3 g/dl
MCV	79 fl
Platelets	$256 \times 10^9/l$
WBC	$7 \times 10^9/l$
Creatinine	88 $\mu\text{mol/L}$
Na+	140 mmol/L
K+	3.6 mmol/L
ANA	Positive
Anti dsDNA	Negative
Chest X-ray	Blunting of costophrenic angles bilaterally
Complements C3 & C4	normal

What investigation is most likely to confirm the suspected diagnosis?

--	--

	Serum rheumatoid factor, anti Ro, anti La
	Renal biopsy
	Wrist X-ray
	Anti histone antibody
	Repeat serum anti dsDNA to rule out lab error

Dashboard

Question 152 of 156

An 82-year-old man is referred to neurology clinic with slowness. He presented with his wife who reported that he has been becoming progressively slower in his movements and his facial expressions have become more limited. His symptoms have progressed rapidly following the onset of dizziness a few weeks ago. He has a past medical history of type two diabetes, hypertension, high cholesterol, previous hemicolectomy for diverticulitis. His current medications include ramipril, atorvastatin, paracetamol, amlodipine, metformin, prochlorperazine and gliclazide.

On examination, he has a coarse bilateral tremor at rest, and rigidity in both arms. He has a slow gait as well. What is the most likely diagnosis?

	Parkinson's disease
	Drug-induced parkinsonism
	Multi-system atrophy
	Vascular parkinsonism
	Wilson's disease

Loss of pigmented cells in Parkinson's

Question 153 of 156

□ □

A 19 year old girl is brought to the Emergency Department by a friend. She is a first year university student and her friends are concerned her behaviour has altered in the past few weeks. On assessment she is confused with an AMTS of 6/10. She has a flat affect. Cardiorespiratory examination is normal although the respiratory rate is 22 at rest. Oxygen saturations are 97% on air. Heart rate is 85bpm regular and blood pressure is 100/55 mmHg.

Examination of her neurological system reveals prominent paraesthesia in both feet with absent vibration sense and proprioception. The ankle and knee reflexes are absent and plantar responses are extensor. There is mild distal weakness in the legs with MRC grading 4/5. Examination of the cranial nerves shows no evidence of nystagmus but visual acuity is reduced to 6/20 bilaterally. She has an ataxic gait.

Her medical history is significant only for coeliac disease and she is taking no regular medications.

Routine blood results show:

Haemoglobin	7.6g/L	Sodium	137mmol/L	Magnesium	0.81mmol/L
Cell volume	103.2fL	Potassium	4.6mmol/L	CRP	4.5mg/L
White cells	5.9x10 ⁹ /L	Urea	1.9mmol/L	Thyroid tests	Normal
Neutrophils	4.0x10 ⁹ /L	Creatinine	55mol/L	HIV	Negative
Lymphocytes	1.9x10 ⁹ /L	Calcium (corr)	2.43mmol/L	Syphilis	Negative
Platelets	300x10 ⁹ /L	Phosphate	1.01mmol/L		

The patient's friend tells you she has recently started using recreational party drugs.

Which of the following inhaled recreational drugs most explains the above picture?

	Crack (cocaine)
	H (heroin)

	Hippie crack (nitrous oxide)
	Poppers (amyl nitrate)
	Spice (synthetic cannabinoid)

Question 153 of 156

A 19 year old girl is brought to the Emergency Department by a friend. She is a first year university student and her friends are concerned her behaviour has altered in the past few weeks. On assessment she is confused with an AMTS of 6/10. She has a flat affect. Cardiorespiratory examination is normal although the respiratory rate is 22 at rest. Oxygen saturations are 97% on air. Heart rate is 85bpm regular and blood pressure is 100/55 mmHg.

Examination of her neurological system reveals prominent paraesthesia in both feet with absent vibration sense and proprioception. The ankle and knee reflexes are absent and plantar responses are extensor. There is mild distal weakness in the legs with MRC grading 4/5. Examination of the cranial nerves shows no evidence of nystagmus but visual acuity is reduced to 6/20 bilaterally. She has an ataxic gait.

Her medical history is significant only for coeliac disease and she is taking no regular medications.

Routine blood results show:

Haemoglobin	7.6g/L	Sodium	137mmol/L	Magnesium	0.81mmol/L
Cell volume	103.2fL	Potassium	4.6mmol/L	CRP	4.5mg/L
White cells	$5.9 \times 10^9/L$	Urea	1.9mmol/L	Thyroid tests	Normal
Neutrophils	$4.0 \times 10^9/L$	Creatinine	55mol/L	HIV	Negative
Lymphocytes	$1.9 \times 10^9/L$	Calcium (corr)	2.43mmol/L	Syphilis	Negative
Platelets	$300 \times 10^9/L$	Phosphate	1.01mmol/L		

The patient's friend tells you she has recently started using recreational party drugs.

Which of the following inhaled recreational drugs most explains the above picture?

□ Question 154 of 156

A 19-year-old male is found collapsed in a dark alley. He is of no known abode. He is very drowsy but oriented to person, place and time with a Glasgow coma scale of 14/15 (E3, V5, M6). He smells of alcohol but denies having consumed any. His clinical examination is significant for impairment in visual acuity bilaterally. He has a tremor of his outstretched hands but the rest of his examination is normal. His blood pressure is 145/76mmHg with a pulse of 101/min regular, respiratory rate of 22/min and an oxygen saturation of 95% on room air.

Investigations:

Hb	11.3 g/dl
MCV	102 fl
Platelets	$110 \times 10^9/l$
WBC	$12 \times 10^9/l$
Creatinine	117 $\mu\text{mol/L}$
Urea	9 $\mu\text{mol/L}$
Na ⁺	146 mmol/L
K ⁺	5.4 mmol/L
CL ⁻	109 mmol/L

Arterial blood gas:

pH	7.21
PaO ₂	10.9 kPa
PaCO ₂	4.2 kPa
HCO ₃	16 mEq/L

Considering the ingested toxin, what is the next best step in your management?

	Fomepizole
	N-acetyl cysteine
	Activated charcoal
	Gastric lavage
	Sodium bicarbonate

Question 155 of 156

□ □

A 24-year-old woman attends the respiratory clinic for a review of her asthma treatment. The patient reported that overall, her symptoms of asthma had been well controlled in the 6 months since her last review. She had not suffered any significant exacerbations of her asthma in that time and felt she was required to use her salbutamol inhaler only around once per week (which represented a significant improvement over her normal control). The patient also reported that she was now 3 months pregnant, and had just had an unremarkable 12-week ultrasound. While she had not been planning to have a baby, the patient reported being very happy about it, and she was keen to maximise her health during this time.

The patient had a long-standing diagnosis of asthma, with her first presentations during early childhood. While the illness had only caused mild symptoms between the ages of 10 and 15 years, the patient had suffered several severe exacerbations of asthma in her late teenage years, coinciding with the time when the patient had become a regular smoker. The patient did not report any other significant on-going health problems or past medical history. In particular, she denied a history of seizures, high blood pressure or mental health problems.

The patient's current asthma treatment was a salmeterol-fluticasone combination inhaler (Seretide Accuhaler 250), one puff twice daily. She was also prescribed a metered-dose salbutamol inhaler for use as required. The patient had no history of drug allergies.

The patient reported that she continued to be a regular cigarette smoker. Since finding out she was pregnant, she had managed to reduce her regular intake to 12 cigarettes per day, reduced from her previous typical intake of 20 cigarettes per day. The patient was motivated to use her pregnancy as a motivating factor to stop smoking permanently, and during the clinic asked about medication to assist her with quitting.

What is the appropriate drug treatment strategy to assist this patient to stop smoking?

	Nicotine replacement patch with short-acting nicotine replacement
	Varenicline
	No drug treatment options available
	Bupropion
